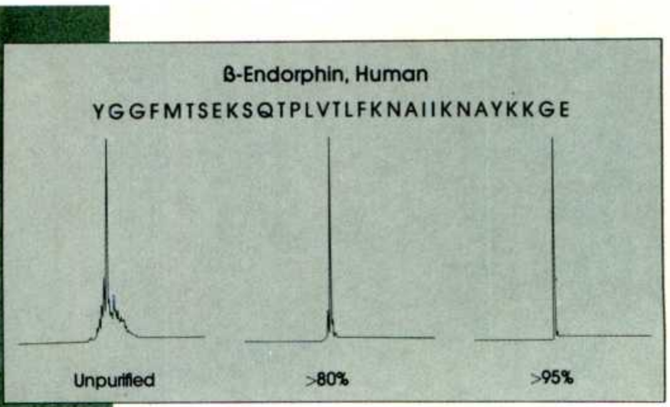
ANTIBODY PRODUCTION IN TRANSGENIC PLANTS

CELL BIOLOGY
product review

NOW Purified Peptides

MPS specializes in quality, custom peptide synthesis . . . so you don't have to!

In order to meet the differing needs of individual researchers, we are now offering three grades of peptides: unpurified, >80% purity and >95% purity. Additionally, for those using peptides to raise anti-peptide antibodies, MPS also provides a peptide carrier conjugation service. Call us with your questions or if you would like a complete price list.



COMPARE OUR PRICES

MPS is offering custom peptides at the extraordinary prices listed below.

		Guaranteed Purity Level	
	Unpurified	>80%	>95%
Quantity	50-100 mg	30-50 mg	20-30 mg
10 mer	$400	$700	$1000
15 mer	$550	$850	$1150
20 mer	$800	$1200	$1600

CAN YOU SYNTHESIZE & PURIFY PEPTIDES FOR LESS?

Before you buy an automated peptide synthesizer, you should consider the actual cost for in-house synthesis which includes the cost of reagents, personnel, service contracts, analysis, purification, waste disposal, laboratory space, downtime and, of course, the initial cost of the synthesizer.

Multiple Peptide Systems

10955 John Jay Hopkins Drive, San Diego, CA 92121 USA

Telephone (619) 455-3710
FAX (619) 455-3713
Outside California (800) 338-4965

MPS also provides a unique HF Cleavage Apparatus and a complete HF Cleavage Service.

PRECISE CONTROL OF REACTIONS

FULLY PROGRAMMABLE DRI-BLOCK® TEMPERATURE CYCLER PHC-2

This latest programmable Dri-Block® temperature cycler PHC-2 has a powerful microprocessor programming capability yet is designed for simplicity of operation. It is now possible to link programmes, hold temperatures for long periods choose four ramp rates up and down and recall temperatures and times from the PHC-2 memory. Two models are available for use with either 0.5 ml or 1.5 ml microcentrifuge tubes.

- Temperature range 0°C–99°C
- Fast temperature change
- Wide and variable number of segments, programmes and cycles – limited only by memory capacity.
- Four user selectable up/down ramp rates
- 99 hour maximum hold time
- Remote sensor in dummy tube to read sample temperature and initiate programme timing.
- Block uniformity 3°C
- RS232 outlet/centronics printer output
- 54×0.5 ml or 24×1.5 ml microcentrifuge tubes
- Water cooled with separate connection for end of programme below ambient cooling
- Temperatures and times held in memory for recall to screen or printer

PHC–1

For less sophisticated programming requirements the alternative model PHC-1 is a simple to use heat/cool unit providing a repeatable cycle of up to three independent temperatures and dwell times. A standard aluminium block will accept up to 54×0.5 ml capped microcentrifuge tubes.

ANTIBODY PRODUCTION IN TRANSGENIC PLANTS
CELL BIOLOGY product review

nature

2 November 1989

Vol. 342 Issue no. 6245

◀ Transgenic plants bearing genes for immunoglobin light and heavy chains are able to assemble functional antibodies. The expression of antibodies in plants could be of both scientific and practical value. The cover shows a BALB/c mouse and transgenic tobacco plant. See page 76.

THIS WEEK

Oil shock

Petroleum-like deposits associated with hydrothermal vents beneath the Gulf of California are shown by radiocarbon dating to be geologically 'young', less than 5,000 years old, but to have a structure similar to conventionally exploited crude oils which are formed over much longer timescales. Page 65.

Sunspot data eclipsed?

A new computer model of the global troposphere suggests that the internal dynamics of the atmosphere can produce variability in the period range often attributed to solar influences. 'External' factors need not be invoked to explain variations, so 30 years of studies of sunspot–weather correlations may be due for reappraisal. Pages 53 and 15.

Muscle-bound

The nematode protein 'twitchin' is a member of a class of very large muscle proteins, and plays an important part in the control of muscular contractility. The sequence of this protein reveals a simple pattern of internal repeats based on sequence motifs with surprising similarities to immunoglobulins and cell adhesion molecules. Page 45.

The $InsP_3$ receptor

The cloning and sequencing of the cDNA of glycoprotein P_{400} from cerebellar Purkinje neurons provides insights into the structure of the receptor for inositol 1,4,5-trisphosphate ($InsP_3$), second messenger in many cells including neurons. Article, page 32. On page 87 it is shown that $InsP_3$ promotes calcium transport into vesicles reconstituted with its receptor protein, suggesting that $InsP_3$-stimulated release of intercellular calcium is mediated by ligand-gated calcium channels. See also page 16.

Level pegging

Lake Tanganyika, the second deepest lake in the world and probably one of the oldest, has been subject to marked lake-level fluctuations. New datings, derived from diatom analysis of cores extending back beyond the limits of the radiocarbon timescale, pin down the depth variations more accurately than previously possible, allowing comparisons with global sea level and climate trends. Page 57.

Decisive step

The phosphorylation state of the product of the cell-cycle gene *cdc2*, protein kinase pp34, directly determines entry into mitosis, a key step in regulating the eukaryotic cell cycle. Article, page 39, News and Views page 14.

Fifth force not needed

Anomalous gravity measurements, previously attributed to the existence of a mysterious 'fifth force', can be explained more simply by invoking geologically reasonable density variations underground. See page 29.

Strategy for repair

DNA repair in *E. coli* occurs preferentially on the transcribed strand during active transcription of the *lac* operon, suggesting that nucleotide excision and repair are coupled, page 95.

Black Sea bugs

The existence of high concentrations of bacteriochlorophylls in the chemocline of the Black Sea suggests that anaerobic photosynthesis could contribute to primary production in the Black Sea carbon cycle. Page 69.

Bang up to date

The notion that Big Bang cosmologies imply that time 'began' is challenged, page 23.

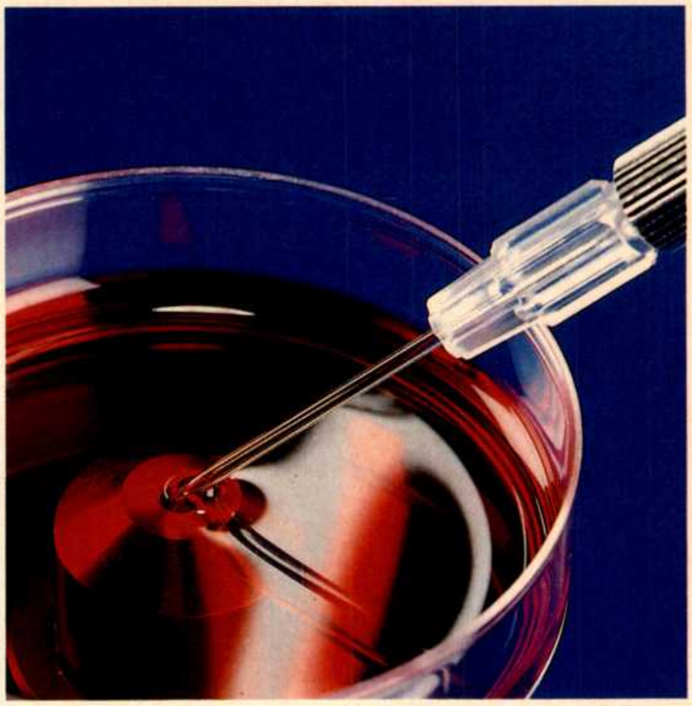
ECET Femtotip®

The tip-top standard capillary

Our tip for microinjection

The ECET Femtotip has the top form for microinjection. The design and outlet diameter (0.5 ± 0.2 µm) of this standard capillary are optimized for accurate microinjection in tissue culture cells. You can start microinjection at any time. The hazard of blockages is reduced to a minimum with Eppendorf's precisely designed Femtotips.



Simplified operation

With the aid of the Eppendorf Microloader, all capillaries can be filled with filament. The Microloader is a very finely pulled pipette tip that fits Eppendorf Pipettes 4700 and 4710. It places the liquid to be injected near to the capillary tip. By keeping the path of the injection liquid to the capillary tip as short as possible, you minimize adsorption, aggregation and concentration effects. Therefore, you can even handle smallest volumes with outstanding precision.

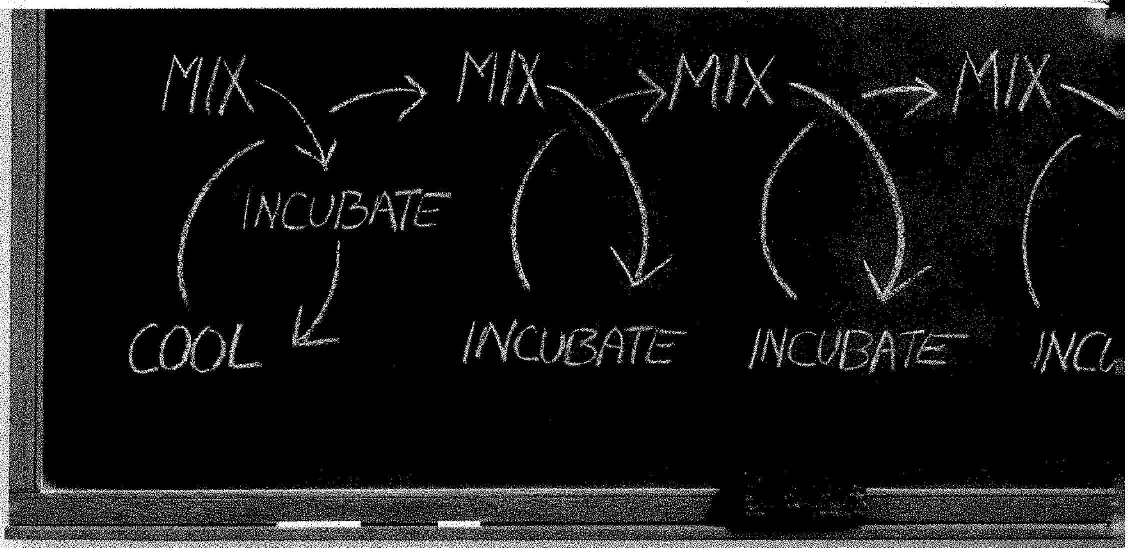
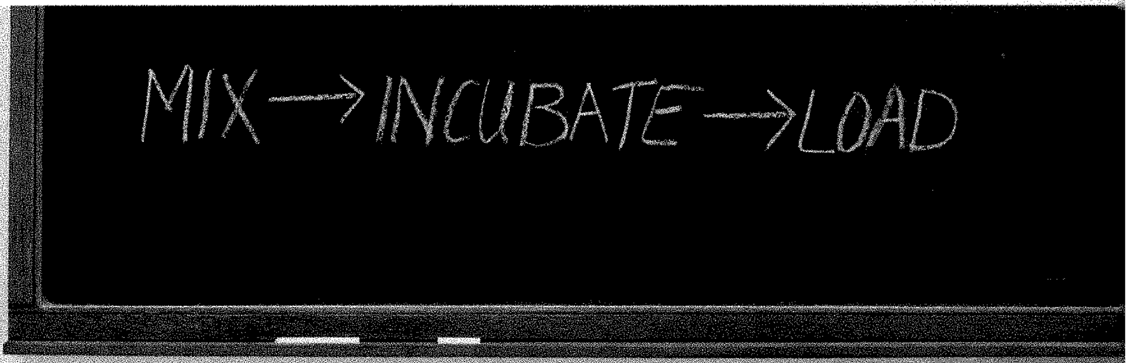
If sequencing has you going around in circles...



let *FASTaq*™ straighten you out.



Introducing the *FASTaq* sequencing biosystem. The first single incubation protocol.

Finally, there's an end to the mix/incubate/cool cycle. With *FASTaq*, you just mix, incubate once and load. *FASTaq* can cut up to half an hour and up to seven steps from your preparation time while leaving less to go wrong. Best of all, you can walk away while its incubating — and use the time to get more things done.

The *Thermus aquaticus* polymerase actively catalyzes polymerization at temperatures exceeding 70°C. These higher temperatures denature virtually all template secondary structures and hairpins that cause most data errors. You get crisp, clear, accurate data every time.

Find out more about the *FASTaq* sequencing biosystem. Call or write today. . .and straighten yourself out.

Call or write.

Engineered to outlast the Great Pyramid

When the ancient Egyptians built their pyramids they had to take the long term view, and so engineered on a massive scale. Their engineers understood the objectives, and worked out the solutions from there. The results are plain to see thousands of years later. ☐ The engineers from UK Nirex Ltd. also have to take a long term view and engineer on a huge scale to make sure Britain's low and intermediate-level radioactive waste is kept safely out of man's environment while it fades away. ☐ Although the pyramids have stood for thousands of years we need to do even better, and so will put all our impressive engineering deep underground, at a thoroughly researched and understood site, where our technology will be backed up by the natural barrier of hundreds of metres of solid rock. ☐ This project will cost at least £1.6 billion and will serve the country's needs for 50 years. ☐ For further information write to The Information Office, UK Nirex Ltd., Curie Avenue, Harwell, Didcot, Oxfordshire, OX11 0RH. Or telephone Peter Curd on 0235 833009.

CYTOKINE MAPPing™ by PCR†

Cataloging Human Cytokine mRNA by *M*essage *A*mplification *P*henoty*P*ing

GeneAmp™ PCR

30 Cycles

Figure 1.

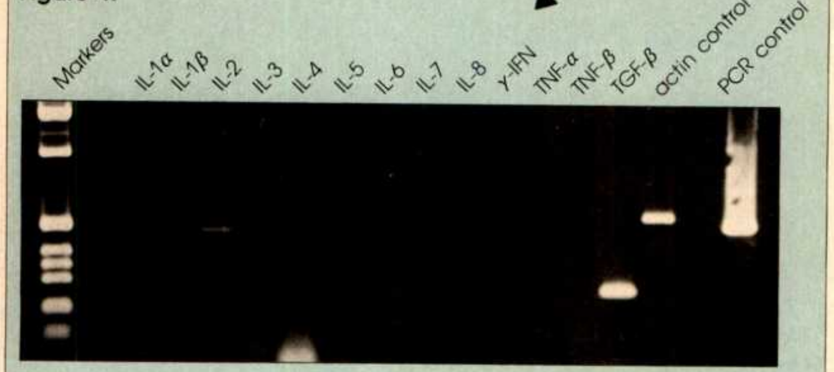

Figure 2.

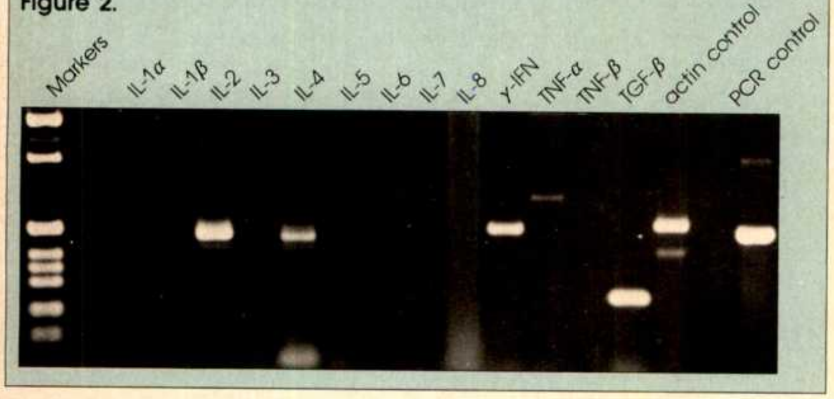

+
Cytokine PRI-MATE™ Amplimers

RNA from 10^6 resting HUT 78 T lymphoma cells was reverse-transcribed into cDNA, aliquots with MAPPing PRI-MATES were subjected to 30 cycles of GeneAmp PCR amplification and visualized by gel analysis. Bands indicate expression of IL-2, γ-IFN, TNF-α, and TGF-β. (Figure 1)

The same procedures were carried out using PHA-activated HUT 78 T lymphoma cells (2 hours). Bands indicate IL-2, IL-4, γ-IFN, TNF-α, and TGF-β. (Figure 2)

Cataloging Human Cytokine mRNA by MAPPing using GeneAmp PCR and Cytokine PRI-MATES is a rapid, yet sensitive technique for the simultaneous analysis of an entire array of mRNAs from a small quantity of cells.

Starting with even a single cell and a microprocedure for mRNA isolation, the expression of the array of cytokines in virtually all cell types can be easily identified.

MAPPing may be used for the study of the pathogenesis of various diseases and for the study of cell-specific cytokine mRNA arrays from cell populations such as lymphocytes, NK cells, granulocytes, monocytes, fibroblasts, and tumor cell lines.

16 PRI-MATE Amplimer Sets are now available:

- Interleukin 1-α through Interleukin 8
- Interferon-γ
- Tumor Necrosis Factors α and β
- CD4, CD8, IL-2, and IL-6 Receptors
- β-actin PCR control

Unlimited affinity for FPLC®

Pharmacia LKB, established leader in the field of affinity gels, introduces yet another first: N-hydroxysuccinimide (NHS)-activated Superose®, for high performance affinity chromatography with FPLC.

The addition of this new gel expands our existing range of prepacked columns for affinity chromatography - Protein G Superose, Protein A Superose and Chelating Superose - and gives unmatched versatility for ligand immobilisation. Now, with NHS-activated Superose you can obtain a high performance affinity media to suit your particular application, for example separation of receptors, antibodies, enzymes and hormones.

Our affinity gels show low non-specific interaction and negligible ligand leakage. They are based on Superose 12, the well-known high performance agarose hydrophilic matrix (13 μm), with high chemical stability over a broad pH range.

Prepacked in glass columns, Pharmacia LKB affinity gels are easy to use. They give reproducible results with high recovery and purity, and when used with FPLC System introduce a number of unique, automated features such as: coupling of ligands to NHS-activated Superose, column regeneration, pH adjustment of eluted fractions, column/buffer switching and method optimisation.

Finally, what could complement the affinity package better than FPLCmanager. The software designed to accelerate and enhance the evaluation and reporting capability of automated FPLC.

High performance affinity chromatography with FPLC System. Contact a representative today and see for yourself how unlimited your affinity separations can be.

We help you manage biomolecules.

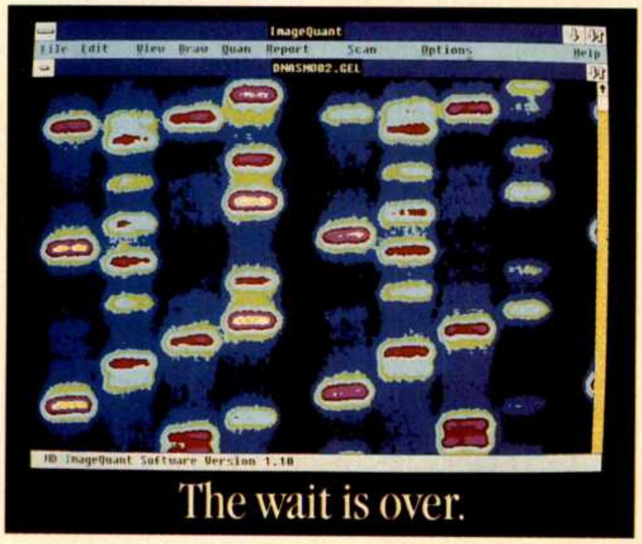
WAITING FOR SOMETHING TO DEVELOP IN AUTORADIOGRAPHY?

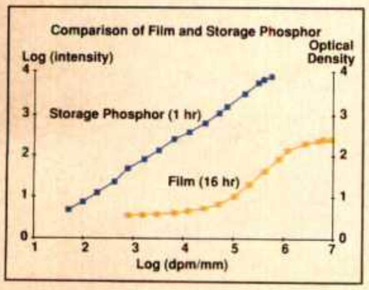


ImageQuant
File Edit View Draw Quan Report Scan Options Help
DNASM002.GEL
HD ImageQuant Software Version 1.10

The wait is over.

Our new PhosphorImager is more than 10 times faster than conventional autoradiography and up to 100 times more sensitive.

The PhosphorImager is an exciting new concept in autoradiography for gels, dot blots, slot blots or any other radioactive sample. Instead of x-ray film, it uses innovative storage phosphor screens that capture virtually all the energy of beta particles, x-rays and gamma rays. So exposure times are shorter. And the linear dynamic range is more than 400 times greater.



There are no darkrooms or processing chemicals to deal with, either. After the screens are exposed, the PhosphorImager scans them with a tightly focused HeNe laser. The stored energy is released, collected, digitized, and the raw data is stored on the hard disk, ready for analysis using Molecular Dynamics' field-proven ImageQuant™ software.

Since all the data is stored on disk, you can reprocess data or print out publication-quality results whenever the need arises. And the phosphor screens can be reused thousands of times for high-resolution imaging.

Find out about the latest development in autoradiography.

For complete information on the new PhosphorImager, call us today. There's no reason to wait any longer.

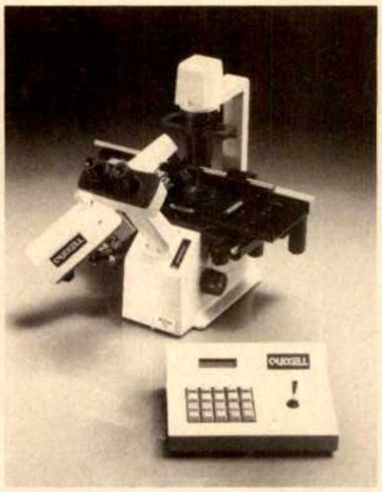
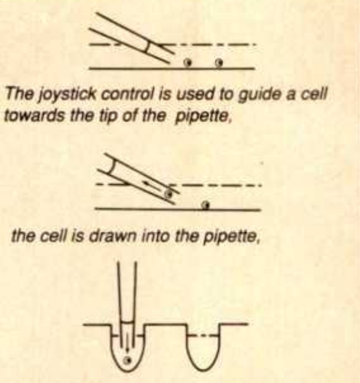
Introducing... QUIXELL CELL TRANSFER SYSTEM

► ***QUIXELL*** is a revolutionary new system for the rapid collection and transfer of individual cells, clones and other organisms from one vessel to another. The unique positive displacement micro pipette makes possible the controlled collection of a cell while remaining under full observation. a single collect/transfer operation takes only seconds allowing a microtiter tray to be rapidly seeded with individual cells. A wide range of pipette diameters are available to suit multiple applications.





The joystick control is used to guide a cell towards the tip of the pipette,

the cell is drawn into the pipette,

and a single keypress transfers the cell to a well in the microtiter tray. The system is now ready to collect the next cell.

Introducing... *Autograph* RADIO ISOTOPE IMAGING SYSTEM

► ***AUTOGRAPH*** represents a breakthrough in digital imaging technology for the rapid evaluation of radio-isotope labels in chromatography gels, blots, tissue sections and similar samples.
The system is able to form an image at least fifty times faster than film thus providing conclusive experimental data in minutes rather than days or weeks. Extensive computer imaging software and display capabilities combined with extremely low background counts provide the capability of resolving many more 'shades of grey' than film making it possible to resolve even the weakest of radio-isotope concentrations.
All software is personal computer based and operates with a user friendly 'pull down' menu environment. Further applications software provides full quantification facilities for even the most complex images.

Developed and manufactured by Oxford Positron Systems Ltd.

Technical Specifications

- Live area : 210 mm x 210 mm
- Spatial Resolution : 1 mm
- Sensitivity :
  19 dpm in sq cm of ^{14}C in 6 min
  Background : 1.7 cpm per cm^2
- Chamber gas:
- Argon 95%, Carbon Dioxide 4%, Isobutane 1%
  Isotopes: ^{32}P ^{35}S ^{14}C ^{125}I. . . .

Software Specifications

- 256 colour display
- Simple user interface based on pull-down menus
- Continuous on-line image formation
- Scaling linear, log, automatic, or user defined
- Automatic user background correction
- Specimen Formats:
  Southern, Northern blots, Dot blots, Microtitre places, tissue sections, TLC plates. . . .
- 1-D or 2-D quantitation, displays and hard copy output
- User defined area, line and point quantification
- Further applications software available.

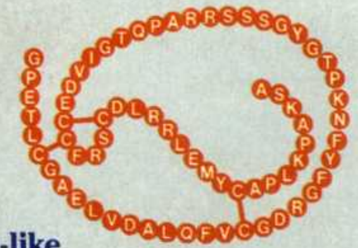
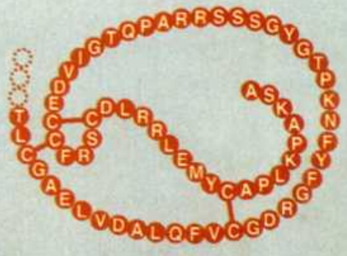
Human cell growth factors for cell growth and differentiation





Insulin-like Growth Factor I (IGF-I)

IGF-I is a 70-amino acid long peptide hormone involved in growth and metabolism. It is one of the most important growth-regulating hormones active after birth; the secretion of IGF-I is influenced both by serum growth hormone levels and by nutritional status.

IGF-I has been shown to influence the growth and differentiation of many types of animal cells, including: ***human*** chondrocytes and adrenergic neuroblastoma cells; ***mouse*** late-stage erythroid precursor cells and mammary epithelial cells; and ***rat*** myoblasts, oligodendrocytes, calvaria cells and thyroid cells.

Specifications

Purity:	>95% by HPLC, gel electrophoresis and amino acid composition
Sp. activity:	>14,000 U/mg by radioreceptor assay using placenta membranes
Quantity:	10 μg, 50 μg, 100 μg, 1 mg, 10 mg and 50 mg.

Brain IGF

Brain IGF is a truncated form of IGF-I (lacking the N-terminal tripeptide) isolated from human foetal and adult brain.

Brain IGF may be important in the growth and metabolism of the central nervous system. It is four times more potent than IGF-I in stimulating DNA synthesis in rat foetal brain cells, and reacts more strongly than IGF-I in cross-reaction on IGF-I receptors in human foetal and adult brain membranes.

Specifications

Purity:	>90% by HPLC, gel electrophoresis and amino acid composition
Sp. activity:	>14,000 U/mg by radioreceptor assay using placenta membranes
Quantity:	10 μg, 25 μg, 50 μg, 100 μg, 1 mg, 10 mg and 50 mg.

Polyclonal antibodies (globulin fraction) to human IGF-I

Polyclonal antibodies to IGF-I have been prepared in New Zealand White rabbits using as immunogen a fusion protein comprising either IGF-I or the C-terminal residues 57–70 of IGF-I linked to a synthetic IgG-binding protein.

IGF-I and Brain IGF react equipotently to antibodies to the C-terminal peptide of IGF-I, whereas Brain IGF is less potent (77%) than IGF-I in cross-reacting to antibodies to whole IGF-I.

Specifications

Titre:	In an immunoradiometric assay, a titre of 1:4,000 for anti-IGF-I and 1:7,000 for anti-IGF-I C-terminal residue
Presentation:	1 ml, freeze-dried from phosphate-buffered saline

One More Reason The ACAS 570 is...
The Cytometer for All Reasons

Reason #1 Interactive Laser Cytometry

You command the power of the laser for new research capabilities such as sorting rare cells for cloning, fluorescence photobleaching, photoactivation, and cellular microsurgery.

Reason #2 Quantitative Fluorescence Measurements

From single to dual label fluorescence measurements, you get **real numbers** for fluorescence quantitation ranging from cell-cell communication and molecular diffusion, to intracellular Ca^{2+} and pH.

Reason #3 Sensitive Fluorescence Measurements

Advanced photometric detection and a focused laser spot give you reliable data from live cells with minimal photobleaching, and without the need for signal averaging.

Reason #4 Comprehensive, Interactive Software

Powerful software teams laser cytometry with advanced computer technology — giving you integrated data acquisition, analysis, and management functions that are easy to learn, and easy to use. You also get a powerful assortment of application based programs specifically designed for the cell biologist.

Reason #5 Versatile Integrated Instrumentation

From fluorescence imaging and cell cloning, to measuring transient Ca^{2+} and pH, the ACAS 570 provides the broadest range of cell and molecular biology applications available in a single instrument.

And now…the ACAS 570 gives you the exceptional resolution and contrast of confocal imaging.

Reason #6 Quantitative Confocal Microscopy

Conventional and confocal fluorescence images of an anti-tubulin stained astrocyte generated on the ACAS 570 Interactive Laser Cytometer.

Next to «in vivo»

The new, compact Gassed Incubator BB 6060 by Heraeus

A Match of High-tech and Experience

Cell or tissue cultures can grow ideally only when exposed to conditions next to «in vivo». Heraeus gassed incubators simulate these natural environmental parameters to the greatest extent.

The physiological values of the organism from which the cells come are reproduced variably and exactly.

Since 1960, Heraeus has accumulated experience in the field of gassed incubators. Practical know-how, gained in cooperation with researchers and scientists, is continually applied to instrument technology.

Use the results of our experience in application technique.

Compact and Customized

Space problems are an everyday nuisance in the laboratory. They are complicated by the fact that many users want to have their »own« incubator. Pathogenes may not be incubated alongside foreign cultures.

The resulting need for a new compact incubator has been met by Heraeus with the BB 6060. The demands of users short of space have been fulfilled by perfected technical design with an inner chamber volume of 60 liters.

Next to «in vivo» – optimal results.

Heraeus

NAT

FOUR WORDS WILL CHANGE THE WAY YOU LOOK AT THE LIFE SCIENCES LITERATURE.

CURRENT CONTENTS ON DISKETTE™

Current Contents on Diskette/Life Sciences changes the way you search.*

Each week you'll receive data diskettes containing the contents pages of the most recent journals published in your field. Using your own customized search profiles, you can locate the information you want in a matter of seconds. Or you can browse at your own pace, viewing contents pages on your computer screen as you go.

...the way you manage data

You'll find that it's easy to manipulate the information you retrieve. From printing out search results...to exporting in four different formats to create your own custom database. Review search results at any time with a simple keystroke or click of the mouse.

...the way you request reprints

When you locate an article you want to see, you don't have to write out your request by hand any more. Simply print out one of the ready-to-mail *Request-A-Print*® forms we've included. *Current Contents on Diskette* automatically fills in the article reprint information along with your name and address.

In a hurry to read an article? Just print out an order for *The Genuine Article*®, ISI's document delivery service— you'll receive the full text within 48 hours from the time we receive your order.

Four weeks free

We're sure you'll discover that searching just got faster and easier. In fact, we'll give you the first four weeks free if you don't agree. Just write "cancel" on the invoice and send it back to ISI. Keep the data diskettes and retrieval software or pass them along to a friend.

Change the way *you* look at the life sciences literature. Call toll-free:

800 336-4474.

HI-TECH
SCIENTIFIC

LEADING THE WORLD IN RAPID REACTION TECHNOLOGY.

Since 1960 Hi-Tech Scientific has been serving the needs of scientists all over the world through the design and manufacture of instruments in the field of Rapid Reaction Technology.

Such quality instruments available include the following:

RAPID REACTION STOPPED-FLOW

SFA-12	Rapid Kinetics Accessory for all Spectrophotometers and Fluorimeters and
SFA-12M	Rapid Kinetics Accessory with Microvolume
SF-41	Low Temperature Cryostopped-Flow Spectrofluorimeter
SF-51	Stopped-Flow Spectrofluorimeter
SF-51MX	Multimixing Stopped-Flow Spectrofluorimeter
TJSF-54	Temperature-Jump and Stopped-Flow Spectrofluorimeter
HPSF-56	High Pressure Stopped-Flow Spectrofluorimeter

RAPID REACTION QUENCHED-FLOW

PQSF-53	Preparative Quench and Stopped-Flow Spectrofluorimeter
PQ-63	Preparative Quencher

DATA HANDLING FOR STOPPED-FLOW

ADS-2	DataPro Software Suite and A/D Converter for Apple IIGS
HS-1	Technical DataPro Software Suite for Hewlett-Packard 310, 320 and 330 Series
IS-1	Rapid Kinetic Software Suite for IBM and IBM compatible computers
ICS-1	Complete data handling package for IBM and IBM compatible computers

SPECTROSCOPY

MG 5000	Hyperscan Rapid Scanning Accessory

TEACHING INSTRUMENTS

for demonstrating the following techniques

SF-1B	Stopped-Flow Spectrometer
TJ-1B	Temperature-Jump Spectrometer
FP-1B	Flash Photolysis Spectrometer
SFA-12	Rapid Kinetics Accessory

FLASH SYSTEMS

XF-10	High Energy Xenon Flash Lamp for the study of Caged Compounds and other Flash Photolysis applications including the adaptation of Stopped-Flow

If your work incorporates any of these areas and you would like to know more about high specification instrumentation that can assist in the quest for better results contact us for a demonstration, information pack, technical reprints or a reference list of over 700 users in 50 countries.

INNOVATION AT THE FRONTIERS OF SCIENCE.

Why did we discontinue the world's most popular vertical electrophoresis cell?

Because we made it better!

Since its introduction in 1984, the original PROTEAN® II cell has enjoyed unparalleled success with more than 10,000 in use. However, good designs are not static, they evolve. Thanks to your input, we have made significant design and performance improvements.

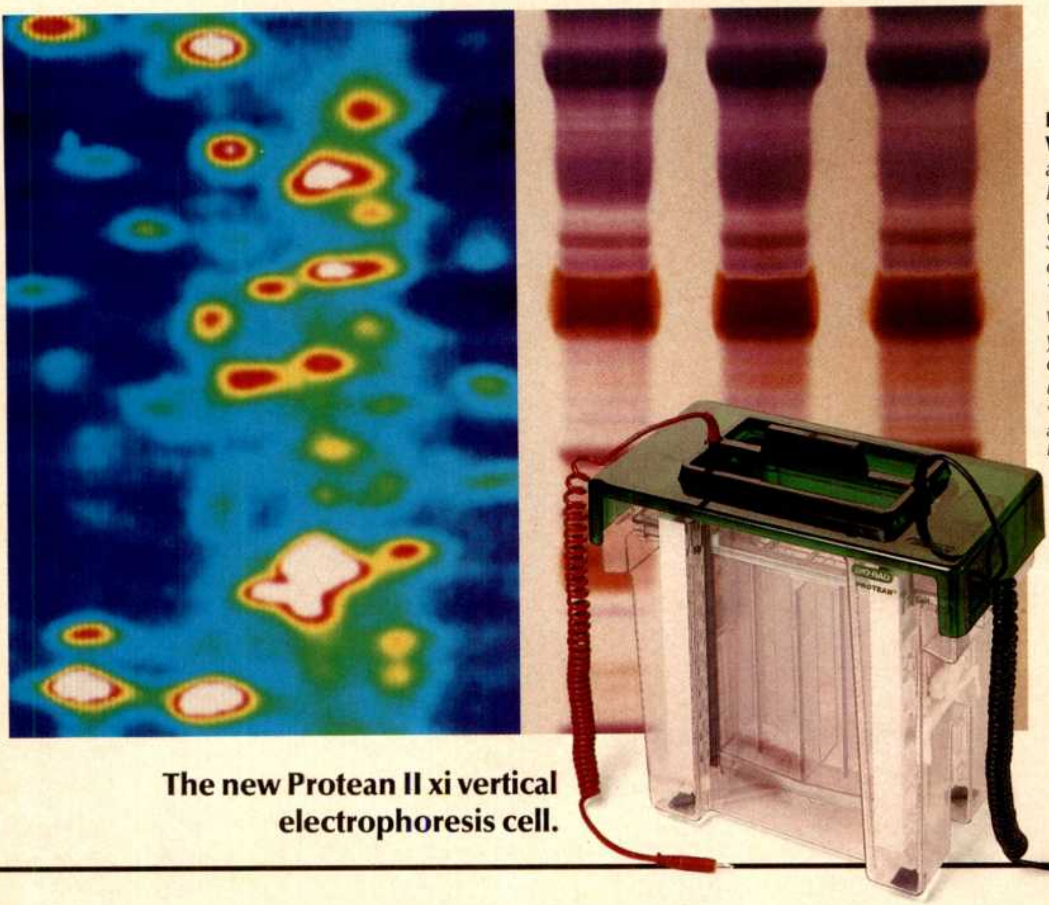
- New state-of-the-art plastic construction for longer life, added strength, and improved chemical resistance.
- New reconfigured cathode for ultra-safe operation
- New alignment cards for greater convenience in assembly
- New softer gasket material for instantaneous leak-free sealing

Plus six other new features to improve ease-of-use, convenience, and versatility!

And, we've kept the features that made the original PROTEAN II cell such an outstanding success, including

- Unprecedented ease of assembly
- Leak-free casting without grease or agarose plugs
- Versatility—runs SDS-PAGE, preparative, gradient, 2D, native and high resolution nucleic acid agarose gels in 16 and 20 cm formats.

Bulletin 1466 tells more. Call or circle the reader service number.



FREE PLATE WASHER? *Well almost. Get our new PROTEAN II xi plate washer system, a $195 value, for only one dollar ($1, 2 DM, 100 yen, 1000 lira, ...)* with purchase of your PROTEAN II xi cell. Offer good until March 31, 1990.*

**This special offer is available through any Bio-Rad office worldwide.*

THINK BIG

Asahi Chemical is far larger and more diversified than most people realize or might even imagine, as one of the world's foremost suppliers of technologies and products for industrial progress.

Products from Asahi Chemical range from fibers, petrochemicals, and plastics to food, housing, and microelectronics, and are an integral part of industry, society, and everyday life. Sixty years of research and development for advanced technology has brought a comprehensive range, and a tradition of exploration and discovery. This pioneer spirit challenges the frontier of knowledge and possibility, and is now at work in biotechnology, optoelectronics, advanced energy processes, and new high performance materials. As a leading corporation with comprehensive, integrated operations in development, manufacturing, and sales, Asahi Chemical will continue to identify and meet the needs of modern society.

M

The technique of electrofusion has generated much controversy, with many scientists claiming that they can't make it work. In reality, electrofusion is a difficult technique with great potential, which must be fine-tuned and carefully matched to the requirements of particular cell lines.

Now, for the first time, a unique "how-to" manual on this elusive technology enables scientists and researchers to recognize and avoid the pitfalls of electrofusion. This volume presents an overview of the most recent advances in the fields of electrofusion and electroporation for the production of both human and mouse monoclonal antibodies. All of the latest protocols and relevant applications are included, to give this volume the laboratory bench place it deserves.

Contents & Contributors:

Electroinjection and Electrofusion in Hypo-osmolar Solution, U. Zimmermann, P. Gessner, M. Wander, University of Wurzburg, FRG; S. K. H. Foung, Stanford University, Stanford, CA. Electroporation of Human Lymphoid Cells: Methods and Applications, Z. L. Jonak, P. Machy, E. Henri, L. McMillan, S. Trullik, D. Matour, R. Greig, Smith Kline & French, King of Prussia, PA. Formation of Hybridomas Secreting Human Monoclonal Antibodies with Mouse-Human Fusion Partners, S. Perkins, Stanford University, Stanford, CA; U. Zimmermann, P. Gessner, University of Wurzburg, FRG; S. K. H. Foung, Stanford University, Stanford, CA. Generating Immortalized Immunoglobulin—Secreting Human Lymphocytes by Recombinant DNA Technology, M. I. Mally, M. C. Glassy, Brunswick Biotechnetic, San Diego, CA. B-Cell Hybridoma Production By Avidin-Biotin Mediated Electrofusion, M. K. Conrad and M. Lo, National Institute on Drug Abuse, Baltimore, MD

HIGH QUALITY RESEARCH REAGENTS

AVIDIN

High quality research grade AVIDIN is purified from chicken egg white. Bulk order available.

EGG YOLK LDL (Low density lipoprotein)

EGG YOLK LDL is prepared from specific pathogen free chicken egg yolk under sterile condition. Recent studies show that LDL have remarkably similar effect with fetal bovine serum.

PROTEIN-NUCLEIC ACID INTERACTION

Volume 10 Topics in Molecular and Structural Biology

Edited by W. Saenger and U. Heinemann.

The book contains articles highlighting the rapidly evolving field of protein-nucleic acid interactions. Individual chapters demonstrate the diversity of biological systems to which protein-nucleic recognition is of central importance.

There are chapters on the interaction of small proteins with DNA and RNA as well as on chromatin organisation. Care has been taken to include accounts of many different experimental approaches to studying the subject. All articles are written by scientists actively involved in the research they describe and considered experts in their respective research areas. The book is well-illustrated and contains extensive bibliographic information to provide easy access to the original literature.

July 1989 £40.00 214pp 234 x 156mm 0-333-45321-2

FROM SEIKAGAKU

OUR CATALOG HAS ENZYMES FROM "A" TO "Z"

*** New Enzyme ***
Calonase (Leech mammalian-type collagenase)

Mucopolysaccharide Lysis
Chondroitinase ABC (Proteus vulgaris)
Chondroitinase ABC Protease Free (Proteus vulgaris)
Chondroitinase AC I Flavo (Flavobacterium heparinum)
Chondroitinase AC II (Arthrobacter aurescens)
Chondroitinase B (Flavobacterium heparinum)
Chondroitinase Kit:
(Chondroitinase ABC, Chondroitinase AC II Arthro)
Chondroitinase-Chondrosulfatase Kit
(Chondroitinase ABC, Chondroitinase AC II Arthro, Chondro-4-Sulfatase, Chondro-6-Sulfatase)
Chondro-4-Sulfatase (Proteus vulgaris)
Chondro-6-Sulfatase (Proteus vulgaris)
Heparinase (Flavobacterium heparinum)
Heparitinase (Flavobacterium heparinum)
Hyaluronidase (Streptomyces hyaluroyticus)
Keratanase (Pseudomonas sp.)

Glycosidases
B-N-Acetylhexosaminidase (Jack Bean)
α-Amylase (Liquefying Type) (Bacillus subtilis)
Endo-B-Galactosidase (Escherichia freundii)
Endoglycosidase D (Streptococcus pneumoniae)
Endoglycosidase H (Streptomyces griseus)
α-Galactosidase (Mortierella vinacea)
B-Galactosidase (Jack Bean)
Glucoamylase (Rhizopus niveus)
Invertase (Candida utilis)
α-Mannosidase (Jack Bean)
B-Mannosidase (Achatina fulica)

Cell Wall Lysis
N-Acetylmuramidase SG (Streptomyces globisporus)
Chitinase-GODO (Aeromonas hydrophila)
Lysozyme- (Egg white)
Zymolyase-20T (Arthrobacter luteus)
Zymolyase-100T (Arthrobacter luteus)

Other Enzymes
Carboxypeptidase W (Wheat)
Glycopeptidase A (Almond)
Lipase (Rhizopus delemar)
Metalloendopeptidase (Grifola frondosa)
Neuraminidase (Streptococcus sp.)
Neuraminidase F
(Sterilized preparation of neuraminidase)
Nuclease S1 (Aspergillus oryzae)
Proline Specific Endopeptidase
(Flavobacterium meningosepticum)
Reverse Transcriptase (Avian myeloblastosis virus)
Uricase (Candida utilis)

Mucopolysaccharides
Unsaturated Chondro-Disaccharide Kit (for PC)
Unsaturated Chondro-Disaccharide Kit (for HPLC)
Unsaturated Dermato/Hyaluro-Disaccharide Kit (for HPLC)
AMPS (Acid Mucopolysaccharide) Kit
Chondroitin
Chondroitin Sulfate B, (Dermatan Sulfate), Na Salt (Pig Skin)
Chondroitin Sulfate C, Na Salt (Shark Cartilage)
Ethylene Glycol Chitin (Substrate for Lysozyme)
Heparan Sulfate Na Salt (Bovine Kidney)
Hyaluronic Acid, Na Salt (Pig Skin)
Keratan Sulfate Na Salt (Bovine Cornea)

European Journal of Cell Biology

50 Volumes in 20 Years

on modern aspects in cell biology

The European Journal of Cell Biology has moved from a leadership position in Germany and Europe to being a renowned international Journal in this fast moving and important field of science. The journal is devoted mainly to studies in cell and molecular biology using animal, plant and protistan cells. Original research papers as well as review articles on aspects of cellular dynamics, differentiation, biochemistry, immunology, and molecular biology in relation to structural data as well as methodologically oriented manuscripts concerning significant technical advances are published in English language. In addition, biomedical manuscripts which are of general cell biological interest are published. A truly international board of editors and co-editors includes scientists from thirteen countries which cover a wide spectrum of cell biology disciplines.

The high publishing standards of German craftsmanship have always characterized EJCB papers. Micrographs, as well as line drawings and tables, are reproduced with the highest quality attainable. Expert reviewing is done with dispatch and with the goal of aiding authors in presenting their findings and conclusions clearly and appropriately.

Papers will be published without page charge (except color prints) within two to four months after their final acceptance.

Abstracts of cell biology meetings published in Supplement issues are distributed at no extra charge to subscribers of the journal.

The format of the journal is 21 × 28 cm.

The issues will subsequently be published bimonthly in volumes of about 400 pages. The price per volume is DM 356,— plus postage, the price for a single issue depends on size, i. e., number of pages.

- no price increase for 1990
- no page charge for publication
- international expert reviewing of manuscripts
- rapid publication within 2 to 4 months
- highest standard for reproduction of micrographs
- Abstracts of cell biology meetings in Supplement issues distributed at no extra charge to subscribers

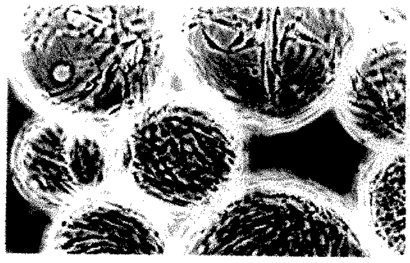
FUNA-COLLAGEN

The new collagen products for tissue cultures and related fields

FUNA-COLLAGEN is a highly purified pyrogen free collagen products manufactured with high technologies under advanced quality controls.

The following products are now available for resesrch purposes.



∗ Collagen solution:

1. Acidic solution, Bovine corium pepsin solubilized type I collagen solution pH 3.0.
2. Acidic solution, Bovine corium type I collagen pH3.0.
3. Neutral solution, Bovine corium pepsin solubilized type I collagen solution pH 7.4.

∗ Permeable collagen membrane and device

∗ Collagen microsphere

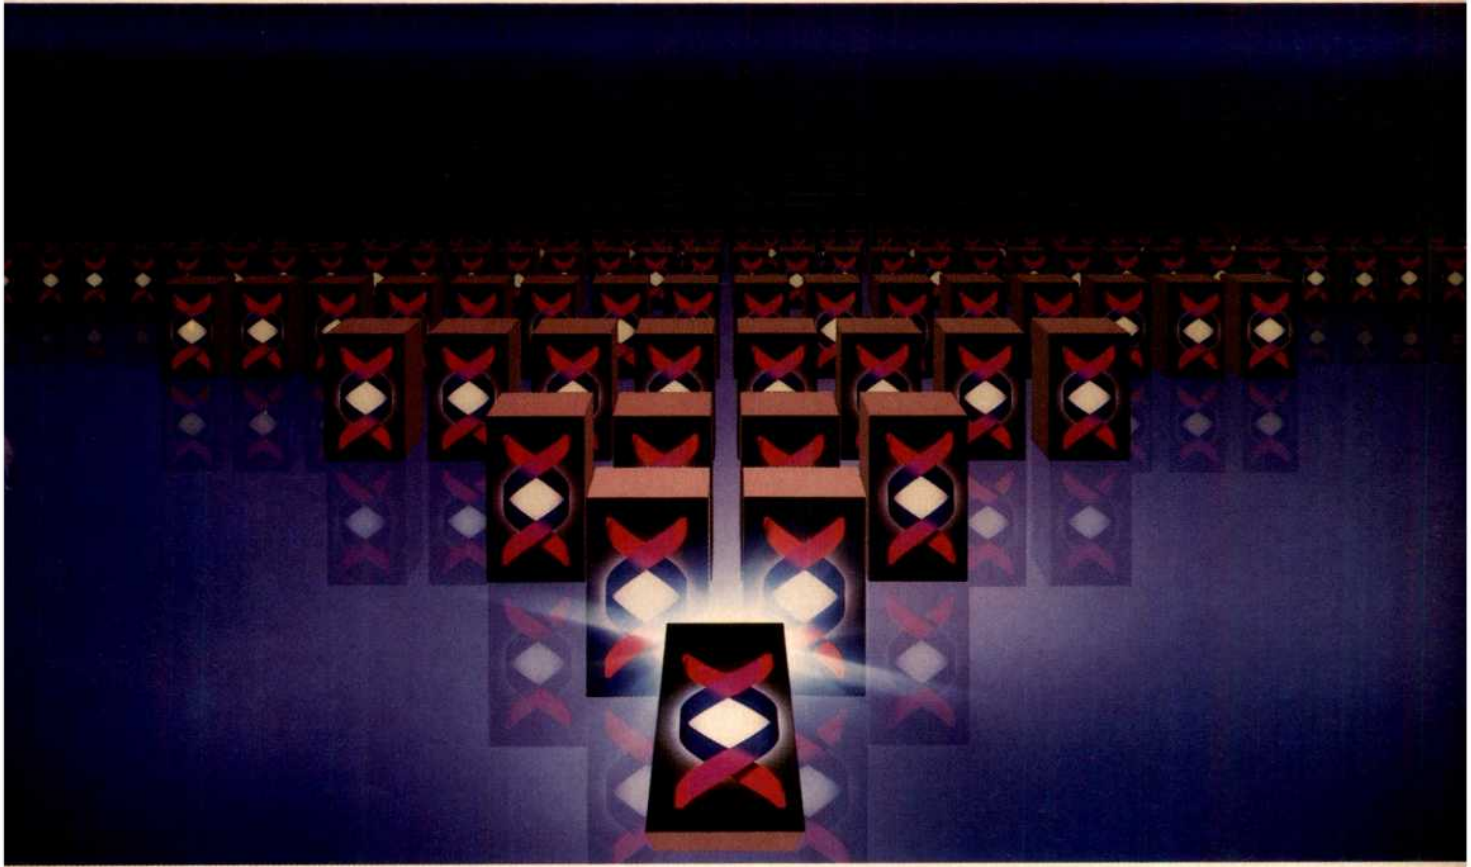
Your choice for PCR products —
Perkin-Elmer Cetus.
The PCR technology leader.



Don't settle for products that try to imitate the revolutionary DNA Amplification System. Ours is the *only* licensed and approved system designed expressly for the patented GeneAmp™ PCR process, pioneered and developed by Cetus scientists.

PROVEN PCR PERFORMANCE

Our DNA Amplification System provides you with performance you can depend on. You'll perform the PCR process quickly and efficiently using our GeneAmp Reagent Kit with recombinant AmpliTaq™ DNA Polymerase. And for easy-to-use, dependable automation, our DNA Thermal Cycler has no peer. Superior technology and proven performance make it the system-of-choice worldwide.

UNMATCHED TECHNICAL SUPPORT

Count on outstanding support for your DNA Amplification System. Like a free instructional video with your DNA Thermal Cycler purchase. Or the toll-free technical support number you can call to get expert answers from our PCR staff. And we'll keep you up to date with PCR protocol developments, applications information, PCR Bibliographies and a subscription to our newsletter, *Amplifications*.

FAST DELIVERY OF TAQ DNA POLYMERASE

Ordering is easy. For overnight delivery of the GeneAmp Kit and AmpliTaq DNA Polymerase, call PE XPRESS at 1-800-762-4002. And we're fully stocked and ready for prompt delivery of DNA Thermal Cyclers.

For more information, contact your local Perkin-Elmer representative. Or, for literature, please call 1-800-762-4000.

Only from Perkin-Elmer Cetus— the PCR Technology Leader.

Nature's Twelfth International Conference

When: November 9-10, 1989
Where: Copley Plaza Hotel
Boston, MA

IT'S SO EASY!

CONFERENCE SESSIONS

1 HUMAN GENETIC DISEASE

James Crow, U. of Winsconsin (chairman); Louis Kunkel, Harvard Medical School; Gerd Utermann, University of Innsbruck; Kenneth Kidd, Yale University; Eric Lander, Whitehead Institute (rapporteur)

2 PROSPECTS FOR GENE THERAPY

Leon Rosenberg, Yale (chairman); Irving Weissman, Stanford University; Richard Mulligan, Whitehead Institute; French Anderson, NIH; David Baltimore, Whitehead Institute (rapporteur)

3 HUMAN GENE RESEARCH:

PANEL DISCUSSION

4 TRANSGENIC MOUSE MODELS

Richard Palmiter, Washington U. (chairman); Douglas Hanahan, University of California SF; Erwin Wagner, IMP Vienna; Ron Evans, Salk Institute; Brigid Hogan, Vanderbilt U. (rapporteur)

5 GENE DISRUPTION AND DEVELOPMENT

Mario Capecchi, U. of Utah (chairman); Fred Alt, Columbia University; Janet Rossant, University of Toronto; Peter Gruss, Max Planck Institute Gottingen; Bruce Alberts, U. of California SF (rapporteur)

Nature has reserved a limited number of rooms at special rates for conferences delegates. When you register we will forward a special hotel reservation card for your convenience.

ATION
UMAN DISEASE
ey Plaza Hotel, Boston, MA

How readily can the genes responsible for predisposition to conditions such as ischaemic heart disease or schizophrenia be identified? What are the prospects of human gene therapy? Are transgenic animals the key to understanding the precise genetic control of development? How much more sophisticated can methods of genetic manipulation and gene identification become?

These are among the major questions that will be addressed by the distinguished speakers at Nature's 1989 conference. A chairman will outline the context and aims of each session, the speakers will review their area of expertise and report the latest advances, and a rapporteur will draw out the implications of each session. There will be a panel discussion of the ethical and legal problems raised by human gene research and therapy. For the convenience of delegates, the second day of the conference will finish in mid-afternoon, whereas the first day will be extended by the panel session followed by a wine and cheese reception.

We expect the conference to sell out well before opening, so urge you to make sure of your place now by returning the form below.

REGISTRATION FEES
Standard rate including reception $350
Special rate for full-time academics and government employees only $300

Sponsor's liability: should the conference be cancelled or postponed for any reason, the sponsor's liability is limited to the return of the registration fee. Cancellation policy: all cancellations must be received in writing. Cancellations before 30 August will be subject to $25 service charge. No refunds will be made after that date. Registrants unable to attend may send a substitute.

Please reserve ____ places for me at Nature's conference 9–10 Nov 1989 Total amound due: US$________

James Baker's brave new world

The US Secretary of State is rightly cock-a-hoop about the prospects for arms control in the near future, but his vision of what follows is incomplete. But it is not too soon to be planning for the post-strategic world.

THE US Secretary of State, Mr James Baker, broke new ground on arms control in his speech in San Francisco last week. Telling how the prospects for far-reaching arms control agreements have been brightened in the past few years, he argued for paying attention now to the arrangements that will be necessary when the agreements now being negotiated have been signed and ratified. At this stage, Baker is doing little more than to think aloud, but it is radical thinking. Can he carry the rest of the US administration with him?

The list of agreements to which lawyers are putting the finishing touches is impressive. That on strategic arms has been made possible by the Soviet government's willingness to decouple the prospective agreement on strategic weapons from the Strategic Defense Initiative (SDI). That, Baker says, will be pursued within the confines of the Anti-Ballistic Missile Treaty. The objective, now, is to eliminate first-strike weapons. On conventional weapons, the superpowers seem to be moving towards an agreement based on the limitation of offensive weapons. A chemical weapons agreement is also almost within sight — the United States will destroy 80 per cent of its stocks on signature, and the Soviet Union will reduce its stocks to the same level, stocks will be reduced by a further factor of ten within eight years of a multilateral treaty and all chemical weapons will be destroyed when all states capable of making them have joined the treaty. It is a breathtaking prospect.

Is it likely to become a reality? Baker's new thinking, as *perestroika* would have it, takes the form of an open calculation of the chances. "We want *perestroika* to succeed", he says; "it would be folly indeed to miss this opportunity." But what if *perestroika* fails, and if the warp of history is rolled back? Then there will be arms control agreements in place, which the Soviet Union will be able to disown only with great difficulty, even risk. And, by implication, arms control agreements may even help *perestroika*. So far, so good.

What follows? One ingredient of the regime to come, in Baker's view, is the strategic *glasnost* provided by the arrangements for verification being written into the arms control treaties. Then, he says, there will be an opportunity also to deal with issues such as the proliferation of missile-making capacity, when the United States and the Soviet Union will be able to make common cause (as, fair play, they have done from the start on nuclear weapons). That, he says, will also be the time to embark on the "institutionalization of a safer world".

But need it wait that long? If *perestroika* has brightened the outlook, it has also deepened some uncertainties, not only in Central Europe, but in the Middle East, the Far East and in South-East Asia. What will happen if Hungary applies to join the European Communities, or seeks to renew its old alliance with Austria? Will the problems of the Middle East spill northwards, through Iran? How will withdrawn-again China react? Where does Japan stand in this changing world? The simple answer is that nobody can tell, which is one of the reasons why present circumstances are cheerful. But that is also a good reason why the "institutionalization" of the safer world cannot be left to the United States and the Soviet Union alone. What Baker needs now, is a political agreement with Western Europe, Japan and the Soviet Union on the future exercise of their political and economic influence. Horse-trading on technology transfer is bound to be an important ingredient, mere money another. □

Diplomacy please

The US human genome project must be mounted internationally, and others must help pay for it.

THE project to sequence the human genome is running into avoidable heavy weather. That is one conclusion drawn from reports last week of the meeting between Dr James Watson, the director of the project for the National Institutes of Health (NIH), and the House of Representatives subcommittee (see *Nature* **341**, 679; 26 October 1989). One teasing issue is that of proprietary rights to whatever sequence emerges. Watson seems not greatly to have exerted himself in disabusing congressmen of the fear that spending $3,000 million of US taxpayers' money would be a gift to the world's biotechnology industry.

In principle, this is a serious issue. Given a complete map of the human genome, commercial companies could scan it for interesting genes or arrangements of genes. Given the possibility that, 15 years from now, much more will be known of how the products of one gene regulate another, a complete sequence may yield even more subtle information about human pathology, and about the usefulness of drugs, synthetic or otherwise. But that is not

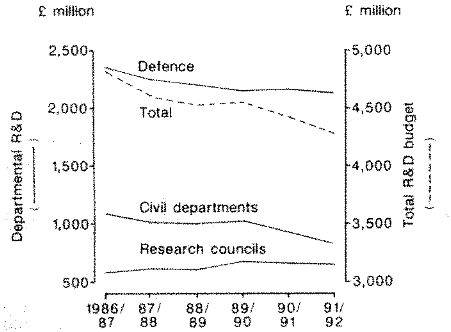
Decline in UK research spending continues

■ 30 per cent fall over five years
■ Britain lags behind competitors

London

British government spending on research and development is projected to fall by up to £250 million over the next three years, according to the latest review by the Cabinet Office Science and Technology Unit. The report also shows that the government is still spending proportionately less on research and development than competitor countries.

The report, *The 1989 Annual Review of Government Funded Research and Development*, predicts that total government expenditure, in cash terms, will fall from £4,616 million in 1987–88 to £4,282 million in 1991–92. In real terms, using the report's GDP (Gross Domestic Product) deflator, this represents a fall of 30 per cent in the government's contribution. The total expenditure figure is split into three blocks: the funds allocated by the Ministry of Defence, other ministries, and the five research councils and the Universities Funding Council (previously the University Grants Committee).



Research and development expenditure by departments, measured in real terms.

The government last year announced plans to switch funds from "near-market" research to basic research. This shift is reflected in the slashing of funds to the ministries. For example, between 1987–88 and 1991–92, the Ministry of Agriculture, Fisheries and Food's research budget will fall from £113.8 million to £93 million, while the Department of Trade and Industry's expenditure will fall from £324 million to £201 million over the same period.

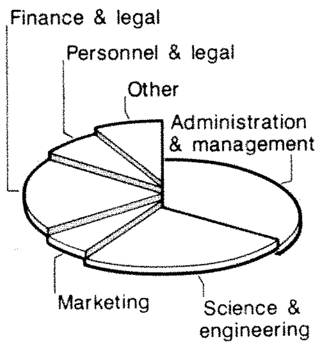
The money saved by cuts in applied research is to be ploughed back into basic research in line with the advice of the Advisory Board for the Research Councils (ABRC) to the Secretary of State for Education and Science. In real terms, the sums available are £13.3 million in 1990–91 and £27.7 million in 1991–92.

There is also to be a transfer of funds from the Universities Funding Council to the research councils. Thus the government's estimate of universities' spending on research out of their general subvention, was £760 million last year, but will fall to £668 million in 1991–92. The overall effect is that, although what is called the Science Budget — the funds spent by the five research councils — will have increased, the total amount of government spending on science will have declined.

Another section of the report shows that Britain is still lagging behind competitors in the proportion of GDP spent on research and development. In 1987, government spending on civil research and development amounted to 0.58 per cent of GDP, compared with 0.91 per cent in France and 0.96 per cent in West Germany. On defence, Britain spent 0.54 per cent whereas the United States spent 0.88 per cent.

The figures also show that, although Britain is getting richer, smaller proportions of GDP are being allocated to research and development each year. Between 1982 and 1987, government spending on civil research and development declined from 0.70 per cent of GDP to only 0.58 per cent. Over the same period, the figure for France rose from 0.84 per cent to 0.91 per cent.

The decline in government support for research has been partly offset by increases in research support from other sources, notably spending by British industry and the activities of international research agencies, especially the European Commission. (The report says that British applicants routinely win more than 20 per cent of the total sums awarded under European Communities' contracts, larger than Britain's 18.9 per cent contribution to the total cost of the Commission's programme.)



First destination of UK science graduates in 1987.

On this basis, the report says that the total value of research and development in Britain financed by all sources amounted to 2.3 per cent of GDP in 1987, the same proportion as four years earlier. During the same period, the corresponding proportions in West Germany increased from 2.5 per cent to 2.8 per cent and, in France, from 2.1 per cent to 2.3 per cent. In Italy over the same period, research spending increased from 1.0 to 1.3 per cent of GDP.

The fall in British government support for research and development is matched by a decline in graduate interest in science careers. The report notes that many science graduates are drifting away from careers in research, preferring service industries. More of the 11,835 science graduates in 1987 chose a job in administration and management than in any other field, including science and engineering.

Only 3,037 graduates chose to stay in research, whereas 4,010 opted for administration and management and 2,125 for legal and financial professions. The popularity of careers in science and engineering among engineers was significantly higher, with 6,412 out of 8,911 graduates staying in the profession.

Ben Webb

AIDS RESEARCH

Have grant, will travel

Bonn

In an attempt to bring some of its best young biologists into AIDS research, West Germany has announced a lucrative fellowship programme. Beginning in 1990, as many as 50 candidates a year will be awarded travel grants and salary (but no automatic research support) to spend two years in a foreign laboratory. Three more years of support will follow after the candidate returns to West Germany.

The programme, which will initially last five years, will be administered by the German Cancer Research Centre (DKFZ) in Heidelberg, with the funds being provided by the West German Research Ministry (BMFT). About DM40 million ($21 million) has been set aside.

Despite the policy of Research Minister Heinz Riesenhuber that no good project should fail for lack of support, the number of suitable applicants for money so far made available for work on AIDS has not fulfilled expectations. Policy-makers are aware that there are structural reasons for the gap (see *Nature* 332, 4; 1989) but are wary of setting up a research centre for AIDS for fear that it would not be flexible enough if research priorities should change.

By reaching out to the younger generation — applicants must be no older than 35 and must have completed a doctorate less than five years before applying — the Research Ministry is trying to encourage future research groups.

Steven Dickman

DIABETES DEATHS

Officials try to allay fears

Washington

HEALTH agencies in the United States and Europe are trying hard to put to rest fears of a connection between the use of human insulin and the deaths of several insulin-dependent diabetics.

The issue, which has caused some alarm in British medical circles in recent weeks, is based upon an apparent increase in the number of deaths, due to "hypoglycaemic unawareness", in diabetics who have switched from animal-derived to human insulin.

Hypoglycaemia, or insulin reaction, strikes diabetics when the level of insulin in their blood is too high relative to their blood sugar level. The hypoglycaemic reaction is normally preceded by numerous physical symptoms such as hunger, sweating and poor coordination, and is reversed by consuming sugar. But anecdotal reports in Britain have suggested that in some diabetics who have switched from animal-derived to human insulin, the warning symptoms of a hypoglycaemic reaction are much less noticeable. This phenomenon has been linked to 17 deaths in Britain in the past year.

No scientifically established link exists between hypoglycaemic unawareness and use of human insulin, but enough concern has already been generated in Britain to have spurred further investigation. As in the United States, most of Britain's 200,000 diabetics have now switched from animal-derived to human insulin. Although some human insulin is manufactured by conversion from animal sources, much of it is synthesized using recombinant DNA technology, a fact that may well have inflamed the fears; human insulin is one of only a few genetically engineered products in wide use.

The UK Committee on the Safety of Medicines announced last month that with the help of the British Diabetic Association (BDA) it would investigate the reports of hypoglycaemic unawareness. In a recent UK survey, 6 per cent of 302 randomly selected diabetics reported diminished awareness of hypoglycaemia after switching from animal to human insulin. An earlier Swiss study, from 1987, reported diminished awareness in more than one-third of the 176 patients interviewed. Meanwhile, the BDA is said to have received some 60 unsolicited letters from patients complaining of hypoglycaemia with human insulin, sometimes with altered awareness.

With concern spreading overseas, the American Diabetes Association last week issued a statement urging people with diabetes "not to overreact". "There are no scientific studies confirming these initial reports", the statement stresses, adding that, given the complexity of mechanisms that warn the body of hypoglycaemia, it "is very unlikely to be due simply to the type of insulin used." Dr Robert E. Silverman, chief of the diabetes programme branch of the US National Institutes of Health (NIH), says that hypoglycaemic unawareness does not seem to be a problem in the United States. Silverman's group is sponsoring a comprehensive long-term clinical study of diabetes, involving some 1,400 diabetic subjects, and so far an increase in hypoglycaemic unawareness "hasn't jumped out of our data", although the issue is not a specific focus of the study.

Silverman is confident that if hypoglycaemic unawareness were a problem among US diabetics, indications would have shown up through the NIH study or in the adverse drug reaction programme sponsored by the US Food and Drug Administration. Although he does not dispute the UK findings, Silverman has reservations about them because they are based upon "retrospective reporting by patients of something that happened in the past". But he says that animal-derived and human insulin are known to have different kinetics of absorption into the bloodstream, and that close monitoring is merited when patients alter their treatment regimens.

Edward West, a spokesperson for Eli Lilly and Co., the largest manufacturer and distributor of human insulin in the United States, warns against what he calls "a great deal of misinterpretation" over the issue, and adds that none of the reported deaths have occurred in patients who were taking insulin manufactured by his company. Nevertheless, West says that his company already incorporated warnings about the potential for altered awareness of hypoglycaemia in its patient literature on human insulin. In response to a request by the British Licensing Authority, all insulin manufacturers in Britain are said to have made the change in their literature as well. **Seth Shulman**

WEATHER FORECASTING

Monsoon prediction model

New Delhi

ACCURATE predictions of the behaviour of the Indian monsoon for the past two years have bestowed a new confidence on the scientists of the Indian Meteorological Department (IMD) and their new long-range forecasting model. Monsoon forecasts have great economic and even political value; the amount of rain that falls from June to September affects not only the agricultural success of large parts of the country but also, as a consequence, their political stability. Earlier efforts to predict monsoon behaviour have, however, been largely fruitless.

The IMD now claims it has a qualitative model good enough to be a useful tool in decision-making. Meterologists say they can predict, two months in advance, not only whether the monsoon will be good or bad but whether total rainfall will be more or less than the normal 88 centimetres. The model is a simplistic one, based on isolated and empirical discoveries of links between a number of regional and global meteorological and oceanic parameters and the monsoon circulation. Fifteen such parameters have been identified as having a historical relationship with monsoon rainfall. There seems to be a link, for example, between the strength of the El Niño phenomenon off the South American coast and the monsoon rainfall in the following year. And extensive Himalayan snow cover in winter, which increases albedo and leads to less continental heating, betokens a poor monsoon that summer.

From a study of monsoon rainfall between 1951 and 1987, IMD meteorologists argue that India has a normal monsoon whenever at least nine of the 15 parameters are favourable. By contrast, 1965 was a year of extreme drought and none of the parameters was favourable that year, whereas in 1955, which saw the heaviest monsoon of this century, only one parameter was unfavourable.

Despite the empirical nature of this model, Vasant Gowariker, secretary to the Department of Science and Technology, says IMD is "quite convinced" that a qualitative prediction of the monsoon can be made simply on the basis of how many of the 15 parameters are favourable. The model was first put to use in 1988, when 13 of the 15 parameters indicated a good monsoon. In May that year, a month before the onset of the monsoon, IMD predicted a monsoon with total rainfall "on the positive side of normal"; the rainfall turned out to be 19 per cent above normal. The following year IMD predicted, this time two months in advance, another good monsoon and, at 30 September 1989, the total rainfall stood at 1.4 per cent above normal. Correct forecasts for two successive years, claims Gowariker, have "validated the utility of our model as a decision making tool". IMD scientists hope to derive quantitative predictions of the monsoon rainfall by weighting the 15 parameters differently. Like any statistical technique, Gowariker says, these models have limitations, "but they are the best available to make long-range forecasts of the monsoon."

NUCLEAR CLEAN-UP

Cynics still unsatisfied

Washington

THE US Department of Energy (DoE), under the leadership of new Energy Secretary James D. Watkins, has attracted public attention and a good deal of praise for its announced determination to clean up the nation's contaminated nuclear-weapons production facilities. But even before it has properly begun, DoE's much publicized five-year environmental plan has come under attack, from private organizations and other government agencies, for being over-ambitious, impractical and even misleading.

Senate hearings on the clean-up plan are not expected until later this month and the period for public comment has not ended, but there is already controversy. Officials from the National Academy of Sciences (NAS) and the Environmental Protection Agency (EPA), as well as a variety of independent technical experts, have set out harsh criticisms of the voluminous plan, which was announced in August and unveiled officially in September (see *Nature* **340**, 416; 1989).

Particularly pointed are comments from the privately funded Natural Resources Defense Council (NRDC), which claims that DoE's new accounting procedures exaggerate the true amount allocated to the environmental clean-up. The group claims that the advertised $19,000-million cost of the five-year plan includes basic operating and maintenance functions at the weapons-production facilities, costs which DoE is obliged to spend anyway and which do not represent any new commitment of money to clean-up operations.

According to Jim Werner of NRDC, the DoE's plan includes routine maintenance items, such as replacing waterline valves, in its budget. Numerous similar examples, he says, argue that a large portion of the plan's budget has "nothing remotely to do with environmental restoration". Branding the situation an "old accounting trick", Werner says that his analysis shows that as much as 60 per cent of the DoE plan's financing is merely money shifted from existing budget categories.

Meanwhile, other agencies have criticised the plan's lack of detail. The NAS Board on Radioactive Waste Management, for example, criticizes DoE for not ordering the contaminated sites according to some sort of priority system. Without such a ranking system, the NAS's review declares, the plan lacks "focused information on the specific, near-term actions that DoE plans to initiate" and risks "promising more than can be delivered".

Senior EPA officials have also objected formally that the plan "lacks specificity and depth". In addition, these officials complain that the DoE has not placed a high enough priority on compliance with current environmental laws in the work that it is doing at present at its contaminated facilities. And finally, the DoE has received sharp criticism for not allocating specific funds for research and development activities despite their stated emphasis on an "aggressive R&D program" devoted to the development of "environmental restoration, treatment, and disposal technologies".

Criticism of the DoE clean-up plan comes despite the overall high marks given to the Energy Secretary by most observers. Since he assumed command at the Energy Department, Watkins has been a highly visible and unstinting advocate of everything from increased science education to keeping alive the Shoreham nuclear power plant in Long Island, New York. Notably, Watkins is given credit even by his critics for his repeated and forceful public assurances that the issues of hazardous and radioactive contamination at the DoE's environmentally plagued facilities will henceforth receive the agency's highest priority.

The NAS report, for example, praises what it terms the "much publicised 'change of culture'" at DoE; this refers to an early speech by Watkins in which he admitted that DoE administrators had in the past tended to evade their responsibilities and to let environmental concerns go unanswered.

Many other commentators similarly endorse Watkins' actions, but some are more cynical. James Beard, of the Washington-based Environmental Policy Institute, for instance, acknowledges that there is a new attitude at DoE, but says it is, so far, "more a change in public relations than policy".

Defending the clean-up plan, Watkins has said that he intends it to be a "living document" subject to periodic review and amendment. This sentiment is reiterated by DoE officials, who claim that the plan must be viewed only as a broad "roadmap" for the first stages of a clean-up programme that DoE believes will take 30 years.

Nevertheless, the extent of the current controversy indicates a widespread scepticism about DoE's management record, as well as concern over the enormous federal resources that will be needed to clean up the 40-years' worth of contamination. One influential congressional staff member underlined the crucial nature of the current debate. "The last thing anyone wants", he says, "is to participate in hearings several years from now about how DoE wasted billions of tax dollars in a flawed clean-up program".

ALASKAN OIL SPILL

Suit and countersuit for Alaska and Exxon

San Francisco

RELATIONS between the state of Alaska and the Exxon Corporation, already strained in the aftermath of the oil spill last March in Prince William Sound (see *Nature* 341, 174; 1989) reached a new level of tension last week when the oil company announced a lawsuit against the state, claiming that Alaskan officials had interfered with the company's clean-up efforts.

The lawsuit, filed in the Superior Court of Alaska and seeking unspecified damages, drew an angry response. "They're just trying to rewrite history for legal reasons", asserted Ernest Piper, special assistant to the governor. He said the claim was "so contrary to fact that nobody even considered it an issue".

Exxon's complaint is actually a counterclaim to a suit already brought against the company by Alaska, which is seeking unspecified punitive and compensatory damages for alleged violations of state, common and general maritime laws.

The counterclaim focuses on an oil-spill contingency plan approved by the state for what is known as Zone 1, the central portion of the sound where most of the 11 million gallons of crude oil were spilled from the Exxon tanker *Valdez* when it struck a reef.

Both sides agree that the plan allowed chemical dispersants to be used at the discretion of the US Coast Guard alone, without prior approval from the state. But Exxon claims that the state nevertheless made known its opposition to the chemicals, which break down oil into microscopic droplets that are easily dispersed by normal tide motions, to the extent that the Coast Guard delayed granting permission for their use.

As a result, says Exxon, most of the oil remained untreated in Zone 1 for two days. By the time approval came, a violent storm had blown the slick out of the area. "It was a foreseeable consequence of the state's preventing the timely use of dispersants that much more oil would wash onto beaches, shorelines and islands and into intertidal and estuarine areas", Exxon said in the suit, which seeks reimbursement from Alaska for the part of the clean-up costs and damage claims caused by the state's alleged actions.

Piper responded that the state did not interfere at all in the clean-up, and that the Coast Guard delayed its approval solely because of unsuitable weather conditions. He said that dispersants work only in agitated seas, and that for the two days in question the seas were so flat and calm it would have been pointless to use them. "The state in no way delayed any decision to use dispersants", he said.

Robert Buderi

INTERNATIONAL COOPERATION

UNESCO on trial in Paris

Paris

THE twenty-fifth general conference of UNESCO (the United Nations Educational, Scientific and Cultural Organisation), now in progress, will be a testing occasion for the organization and for its director-general, Federico Mayor.

The agenda for the month-long (17 October – 16 November) meeting at the Paris headquarters includes Mayor's medium-term plan for 1990–95 and the budget for the next two years. But also in the balance are his efforts over the past two years to carry out reforms designed to persuade the United States, Great Britain and Singapore to rejoin the organization; they left in December 1984 professing unhappiness with UNESCO's effectiveness and political direction.

Since his election two years ago (see *Nature* **329**, 659; 1987), Mayor's liberal style has, for many, been a welcome contrast with that of his autocratic predecessor, Amadou Mahtar M'Bow. He has also proved himself an able diplomat by persuading the Palestine Liberation Organisation to postpone its demand for membership until the next general conference. Without this withdrawal, there would have been no hope that the United States would reconsider its membership.

But within UNESCO, Mayor has been criticized for not going far enough or fast enough in his reforms. And, despite his three meetings with the new US Assistant Secretary of State for International Organisation Affairs, John Bolton, a Congress hearing on UNESCO in September, at which non-governmental organizations and the private sector were invited to testify, made it apparent that Mayor has still not convinced some sectors of the US administration.

At the hearing, Frank Press, former director of the National Science Foundation, Leonard Sussman, author of a recent book on press freedom and Dr Mitchell of the American Council on Education gave testimony on UNESCO which, according to an observer at the hearing, emphasized its potential future role in international cooperation in science. They implied that the United States could no longer afford to stay outside the organization despite its faults. But Bolton, a Bush appointee who came from the hard-nosed Heritage Foundation, maintained that UNESCO still has a long way to go before reforms justify a US return.

It has been difficult for Mayor to achieve real reforms on the questions that were instrumental in the US and British decisions to leave. At the heart of the quarrel was the New World Information and Communications Order (NWICO), M'Bow's attempt to protect developing countries from what was perceived as an unwelcome flood of media attention from industrialized countries. As part of its programme, NWICO effectively endorsed the right of governments to censor critical news reporting.

In his new medium-term plan, Mayor addresses this issue by falling back on the UNESCO constitution, which speaks of the organization's duty to advance the "mutual knowledge and understanding of peoples" by promoting the "free flow of ideas by word and image".

But Africa is UNESCO's main province of concern, and Mayor cannot afford to upset the African delegations; he thus refers to a need for the "balanced dissemination of information", a locution that to sensitive US ears sounds like an echo of NWICO. The way out of this quarrel, says Mayor, is through the notion that the interests of developing countries can best be served by encouraging the development of endogenous communications and media.

Another cause of US irritation was the top-heavy bureaucracy. Deprived of more than a quarter of its regular income by the US walk-out, the organization was forced to cut its staff of 2,800 by 700. But, as Mayor pointed out in his opening address on 16 October, cost-cutting is incompatible with the injection of much-needed new blood. The inability to hire new staff in any quantity means that Mayor has not only had to manage a programme set up by his unpopular predecessor, but has had to do so largely with M'Bow's former staff.

The content of Mayor's medium-term plan has so far met with approval. His "priority of priorities" is to reduce the "unacceptable gap" between the richest and poorest peoples through education programmes. Next year will be International Literacy Year and UNESCO will hold a conference on Education for All in Thailand in March. Other priorities are the promotion of peace through increased cultural exchange and also of "peace with nature" through UNESCO basic science programmes, a plan whose theme is "not to mortgage the very existence of future generations".

But despite Mayor's ambition that UNESCO should "do less, but in greater depth", the organization is faced with severe financial difficulties. Taking account of a shortfall carried over from the last budgetary period, the proposed $372.5 million regular budget for 1990–91 is effectively a decrease in real terms, and is on a level with spending in the early 1970s. This means that the programme for the next two years will be hotly contested.

Developing countries have already resisted a proposed 2.5 per cent increase in members' contributions, and plans to modernize communications equipment are likely to be postponed.

According to John Fobes, US observer at the conference on behalf of the International Social Science Council, the time is right for the United States to return. Now that the communications issue has quietened down, he says, the value of UNESCO as coordinator of international science, technology and education programmes can be appreciated.

"There will be a lot of important conferences on global issues in the next few years and it would be good if UNESCO became a quiet place for an overall look. In the next ten years, UNESCO will be rebuilt and will become a monitor, instead of a do-all and be-all. The world needs that."

Despite Bolton's luke-warm statement in Congress, some influential groups within the United States are in favour of a return. In Britain, the Foreign Office has assured Mayor that the government will review its position once the conference is over.

RAINFOREST DESTRUCTION

Unions turn green in Australia

Sydney

CONCERN over the fate of South-East Asian rainforest has led Australian labour unions to take an interest in ecology. The Building Workers Industrial Union (BWIU) for the state of Victoria, noting the daily loss of 11 square kilometres of Malaysian forest, has banned the use of imported rainforest timber. According to the BWIU, more than one-third of such wood is used to build forms for concrete-pouring, and then discarded.

Domestic timber should be used instead, the union believes, which would provide more jobs for Australians, save endangered species of Asian trees and help native groups such as the Penan tribe of Malaysia whose traditional forest habitat is only a year away from destruction.

The BWIU ban is supported by the Australian Council of Trade Unions, which has announced its intention to end the importation of timber from threatened rainforest areas. The Waterside Workers Federation and the Seamen's Union have begun a series of 24-hour actions to prevent the unloading of timber from ships docking in Australian ports.

But according to Neil Goldsmith of the Plywood Association of Australia, their actions could be counter-productive. The import of rainforest timber is a A$128-million-a-year industry, and disruptive union action could, says Goldsmith, drive up prices and cause the loss of domestic jobs.

Tania Ewing

GLOBAL CLIMATE CHANGE

Equivocation on cooperation

Washington

DESPITE President George Bush's election promises to take the lead in tackling global climate change, his administration has outraged the US Congress and environmental groups by hesitating over whether to send official representatives to an international environmental conference in the Netherlands next week. The White House Domestic Policy Council finally agreed that the president's science adviser, Allan Bromley, should accompany Bill Reilly, the head of the Environmental Protection Agency, to the conference, but, it is said, has not allowed Reilly to invite participants to another conference that would be hosted by the United States next year. A new inter-agency working group set up to develop the administration's policy on global climate change will meet this week to decide whether to support the global climate convention that will be proposed at the Netherlands conference.

The controversy hijacked a hearing of the Senate Committee on Commerce, Science, and Transportation last week whose purpose was ostensibly to consider the nominations of James Wyngaarden, the former director of the National Institutes of Health, and Thomas Ratchford to be associate directors of the Office of Science and Technology Policy (OSTP). Bromley denied that the administration was opposed to negotiating a global climate convention, but emphasized that it would undertake no action until the end of 1990, when the Intergovernmental Panel on Climate Change (IPCC) will have completed its studies. Formed under the auspices of the United Nations Environment Programme and the World Meteorological Organisation, the IPCC is reviewing the scientific evidence for global warming, the social and economic impact of possible climate changes and ways of dealing with the problem.

Senator Albert Gore (Democrat, Tennessee) said he was "extremely disappointed" with the advice Bromley was giving to Bush on this issue after Bromley's refusal to say whether he had initially been opposed to attending the conference or whether he was in favour of negotiating a convention were interpreted as indicating his opposition to both. Although earlier this year Bush signed a declaration at the G-7 economic summit that "strongly advocates" common efforts to limit emissions of carbon dioxide and other greenhouse gases and declares that a global convention on climate change is "urgently required", Bromley said that there was a difference of opinion between the administration and Congress over the definition of 'urgent'. He also said that there was "a substantial distance to go yet" before an adequate understanding of the science of global change would be reached, and quoted a recently revised model from the UK Meteorological Office that reduced the predicted temperature increase for a given addition of carbon dioxide from 5.2 to 1.9 °C after a more sophisticated treatment of cloud behaviour was added. Bromley also emphasized that discussion so far has focused too much on "the input side of the global change equation" and that more studies are needed of the economic consequences of a convention.

Eleven environmental groups, including the Natural Resources Defense Council, the Environmental Defense Fund and the National Audubon Society, offered Bush rather different advice last week on policies to tackle global warming. In a joint declaration, they called on Bush to support a 20 per cent reduction in national carbon-dioxide emissions by the year 2000, an international convention to reduce emissions of greenhouse gases, and the development of a national climate policy. At a hearing of the House of Representatives subcommittee on human rights and international organizations, they all endorsed a bill to coordinate better federal research on climate change through the Committee on Earth Sciences of the OSTP. **Christine McGourty**

ENVIRONMENT

'Hot lab' to be closed over contamination fears

San Francisco

BOWING to growing community concern over toxic contamination, and citing changing business needs, the Rocketdyne Division of the Rockwell International Corporation has decided it will shut down a nuclear laboratory, used for processing radioactive materials, at its Santa Susana Field Laboratory east of Los Angeles.

The decision, announced on 20 October and due take effect exactly a year later, will close a 30-year-old operation. Making the announcement, the company said there had been a change in federal government emphasis away from the liquid-metal fast-breeder reactors, in which Rocketdyne had done specialized contract work, towards light-water reactors.

But Rockwell has also been suffering from revelations that a US Department of Energy survey had found radioactive and chemical contamination of the soil beneath the 2,600-acre Santa Susana site, although no immediate health hazard was declared.

Rocketdyne had originally requested a 10-year extension of its operating licence from the Nuclear Regulatory Commission (NRC), but has now asked for an extension only until 20 October 1990 to allow time for the company to complete its decontamination and decommissioning plan for the facility. Robert Buderi

IVORY TRADE

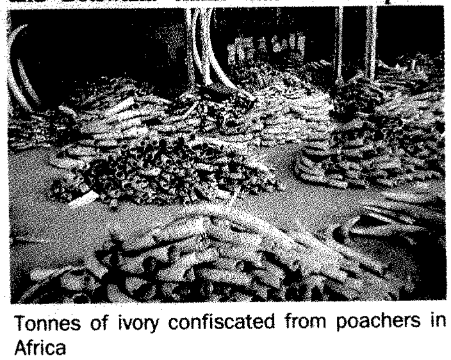
Japan agrees to total ban on imports

Tokyo

JAPAN, the world's largest importer of ivory, has at last agreed to a total ban on ivory imports, at least for the time being.

The Japanese cabinet decide on 20 October to abide by the ban on all imports implemented by the Convention on International Trade in Endangered Species (CITES) at a meeting in Lausanne, Switzerland, earlier in October. Japan at first joined South Africa, Zimbabwe and Botswana in opposing calls for a ban but then abstained at the final vote.

CITES member nations are concerned about rapidly dwindling elephant populations in Africa. But South Africa, Zimbabwe and Botswana claim that their elephant populations are stable or increasing due to conservation measures and wish to continue their lucrative ivory trade.



Tonnes of ivory confiscated from poachers in Africa

In June, the Ministry of International Trade and Industry (MITI) imposed a ban on indirect ivory imports from suppliers in such places as Hong Kong and Singapore. But ivory importers immediately began to stockpile and MITI responded with a 'temporary' total ban in September (*Nature* 341, 270; 1989).

Japan's decision to abide by the CITES ruling, rather than filing a reservation to get around the ban as several African nations plan to do, may in part be due to the fact that Tokyo will host the next CITES meeting in 1991. If imports had continued, Japan would be in a very embarassing position.

But Cecilia Song of TRAFFIC Japan, the trade monitoring wing of the Worldwide Fund for Nature (WWF), says that MITI and the ivory industry hope to resume trade in the near future. The Lausanne agreement allows for resumption of trade after two years if countries can show they have developed an effective strategy to protect elephant populations.

In the meantime, Japan's ivory importers have begun importing mammoth tusks from the Soviet Union. David Swinbanks

BERLIN ACADEMY

Move raises problems

Munich

The uncertain life of the West Berlin Academy of Sciences, which must leave its present home by July next year, seems destined to continue. Criticism from the opposition Social Democrats (SPD) in the *Land* of Hesse may prevent the beleaguered academy from moving there, despite earlier indications that Hesse would be a safe haven. The SPD has set "high hurdles", according to a spokesman, before it will accept the academy.

The academy became a source of discord in Berlin politics after it was pushed through the parliament in 1987 by the conservative Christian Democratic Union (CDU; see *Nature* **329**, 659; 1987). SPD and Green Party politicians, then in the opposition, criticized the academy as a "debating club" with conservative leanings. They vowed to shut the academy once they gained power and, in May this year, the now left-wing government of West Berlin proposed a law to do just that.

With the help of his conservative coalition partners, Hesse science minister Wolfgang Gerhardt (Free Democrat) responded to the Berlin decision in June by offering to "adopt" the academy, and to give it the same financial support as it had been receiving in West Berlin — DM 8.5 million ($4.6 million) a year. This offer needs the approval of the *Land* parliament of Hesse: debate is about to resume, and a final vote is expected in December or January.

But now academy president Horst Albach has said that he will not accept the offer unless the SPD in Hesse also agrees to support the academy. Having already been the victim of a change of government, Albach wants to avoid further uncertainty over the future of the academy.

In response, the SPD in Hesse has demanded a role for political parties in the academy's board of directors as well as strong representation by the universities and research institutes of Hesse. "The academy will be a big financial burden for Hesse", said SPD spokesman Erich Stather. "It is only logical that we want a chance to express our views. What bothers us the most is having the academy floating free of all other scientific institutions." The SPD met in private this week to discuss its position on the academy.

Will the academy be able to accept the terms demanded in Hesse and still remain independent? Academy spokesman Eberhard Vogt calls the problem a case of "Scylla and Charybdis" — the academy is trapped between two hazardous alternatives. Some members of the governing board, which manages the day-to-day affairs of the academy, oppose an industry-financed future for the academy for fear of losing independence.

Nevertheless, the mood in the academy is optimistic. "We have been criticized by conservatives at the University of Frankfurt for being too left-wing, whereas left-wingers in Kassel have said we are too conservative", he said. "So we must be in just the right place politically now." Albach is grateful for the chance to correct the "birth defect" in the way the academy was voted into existence in West Berlin, and he has been crisscrossing Hesse in an attempt to generate support for the new version of the academy.

Ironically, if the academy were to accede to the demands of the SPD in Hesse, it would belatedly live up to the demands that the SPD in West Berlin proposed when its future was discussed in 1986–87. But this is no longer enough for the West Berlin Senate to invite the academy to stay: the Greens would oppose any such move as a violation of their coalition agreement with the SPD.

In a further irony, some activities of the West Berlin academy will probably be allowed to stay in the city if a compromise is reached in Hesse. Hesse is expected to approve the existence of such a "satellite academy" and there is even talk in the West Berlin SPD that some new academy projects would be welcome — a belated tribute to what some are calling the "academy in exile". **Steven Dickman**

BRITISH UNIVERSITIES

United stand in move to greater efficiency

London

Four British universities have appointed a firm of management consultants to try to make them more efficient. In the first move of its kind in higher education, the Universities of Birmingham, Leicester, Loughborough and Warwick have joined forces to maximize their use of resources to offset tighter government budgeting.

The PA Consulting Group will carry out efficiency audits of services such as residences, libraries, maintenance and catering in the four universities.

For the next three years, PA will draw up comparative studies across the four universities and will also look at each area specifically.

Professor Gerald Bernbaum, executive pro-vice-chancellor and registrar of the University of Leicester, said the universities were simply following Universities Funding Council advice to carry out an audit. He said PA would help them "share good practices" and that he was confident the study, which was at a "reasonable cost", would pay for itself in time. Ben Webb

SOUTH AFRICAN EDUCATION

New minister, old problems

Cape Town

In a cabinet reshuffle last month, the new South African president, F.W. de Klerk, announced the return of Dr Gerrit Viljoen as Minister for National Education, with an additional appointment as Minister for Constitutional Development. Viljoen, a graduate of the Universities of Cambridge and Leiden, was professor of Greek at the University of the Witwatersrand in Johannesburg before entering politics, and had previously served as education minister from 1980 to 1984. He was subsequently made Minister of Cooperation and Development, but a year later was effectively moved to the sidelines as Minister of (African) Education and Training, reputedly because he was not a member of ex-President Botha's inner circle. But he was one of de Klerk's staunchest supporters in deposing Botha, and has been rewarded with two of the most crucial portfolios in the new cabinet.

On top of his responsibility for overseeing constitutional reform, Viljoen is faced with the task of defusing the country's growing educational crisis. In 1986, the government declared a commitment to the elimination, over a 10-year period, of racial inequalities in primary and secondary education, but earlier this year was forced to abandon that policy as economically impossible. Education already accounts for 20 per cent of budget spending in South Africa, and in the current economic climate the increases that would be needed for large-scale educational reform are unlikely to materialize. And despite its goal of educational equality, the government is fiercely committed to the provision of separate educational facilities as it regards integration of schooling as an issue too sensitive for the white electorate to accept.

Yet there are signs that this same electorate may be ready to face up to the reality of the situation. The Johannesburg High School for Girls, threatened with closure due to dwindling numbers of white students in its catchment area (which has become a *de facto* mixed area in recent years) decided earlier this year to go private instead. The state has allowed integration in private schools for the past decade, and has also given them limited state subsidies without taking away their charitable status. By allowing a state school to become independent, the government can allow integration without taking overt responsibility.

Academics in South Africa are generally optimistic about Viljoen's appointment, because of his credentials and also because during his first period in the education office universities and museums were well-treated. But he now has more difficult tasks to deal with, and fewer resources to apply to them. Michael Cherry

CHERNOBYL

Lax standards confirmed

London

VIKTOR Bryukhanov, director of the Chernobyl nuclear power station at the time of the 1986 disaster, has at last broken his silence and given an interview to the newspaper *Sotsialisticheskaya Industriya*. Bryukhanov, who is serving a 10-year sentence in a labour colony, had been afraid that any statement he might make would be interpreted as self-justification. "And I was guilty", he admits, "only not as guilty as the court decided." On the night of the ill-conceived experiment that ended in explosion, Bryukhanov was at home in the nearby town of Prypyat.

He was awoken, he says, by a telephone call from the head of the chemical unit who told him only that "something awful has happened — some sort of explosion". Imagining something like a ruptured steam-line, he hurried to the station, but when he saw that the top of number four block was completely missing, "my heart stood still", he says. He telephoned Moscow and tried to order an immediate evacuation, but no one would support him because it was "so firmly fixed in their minds that nothing could happen to the reactor".

Bryukhanov's account confirms the picture which emerged at the post-accident review conference held by the International Atomic Energy Agency of a naive faith in the safety of nuclear power coupled with a neglect of the very rules and procedures on which safety depended. But as director of the Chernobyl power plant from its inception, he is able to reveal the background to this atmosphere of rule-breaking. Starting with a green-field site, he had to oversee the construction not only of the power station itself but also temporary accommodation and later a town for the site-workers. He found himself coping with broken heating systems and failing supplies of fresh vegetables and, unlike the directors of manufacturing plants, he had nothing he could barter to get consumer goods for his workers.

Bryukhanov maintains that without rule-breaking, the Chernobyl station would never have been completed. Electric cables, for example, should have had fire-resistant claddings, but none was available and ordinary cables were used instead. He says he was worried about the situation, but knew that if he made a fuss he would simply be replaced by a new and more amenable director. "It is not within the power of one man to overthrow a system of economic-management relationships which has built up over decades. And he should not be held guilty if in the end he becomes the slave of that system."

But Bryukhanov was found guilty while others in higher places escaped to honourable retirements. Long before the Chernobyl accident, he says, scientists from the Kurchatov Nuclear Energy Institute warned Academician Anatolii Aleksandrov (president of the Academy of Sciences and a leading supporter of nuclear power) of design faults in the RBMK reactor, but nothing was done.

After the accident, the safety systems were tightened up, making it impossible to withdraw many control rods (as was done at Chernobyl) and considerably reducing the automatic shut-down time. Yet Bryukhanov says he is not certain that events similar to those of Chernobyl will not be repeated elsewhere.

Bryukhanov has been heavily criticized since the accident, and the attacks continue. Only last summer, the weekly *Argumenty i Fakty* said that the three operators who carried out the ill-fated experiment on the reactor did not know that pulling out too many rods could cause an explosion. Their superiors did know, the paper said, but they were safely asleep at home.

Whether Bryukhanov did know the full danger and could have stopped the experiment is unclear. He portrays himself as a man in an impossible job, who was made the scapegoat when disaster struck. In the words of Georgii Kopchinskii, head of the Department of Atomic Energy of the Bureau of the Council of Ministers of the USSR, the court "did not judge the man, but the job". **Vera Rich**

CLINICAL RESEARCH

Network of centres better than just one

London

PLANS by the UK Medical Research Council (MRC) to establish a national clinical research centre have been rejected by the Advisory Board for the Research Councils (ABRC), which favours instead a network of provincial research centres. These, says the ABRC, will meet the desired aims of improving the quality of science and the standards of medical training and hospital practice, but will be more cost-effective than the MRC's strategy.

Although Dr David Rees, MRC secretary, welcomed the ABRC's support for the clinical research initiative, he was disappointed that it had not approved the idea of a single centre of excellence. The proposed centre would have been located at Hammersmith Hospital, in association with the Royal Postgraduate Medical School, at an initial estimated cost of £100 million. That figure was later scaled down to £50 million after the ABRC requested that funds be released for other leading clinical research centres in the United Kingdom.

The ABRC recommends that the Hammersmith centre should be fostered, and that the Clinical Research Centre (CRC) at Northwick Park should be closed so that resources can be redirected to the provincial centres. Sir David Phillips, ABRC chairman, in a letter to John MacGregor, Secretary of State for Education and Sciences, says there is a strong case for "enhancing and sustaining" clinical research at the RPMS through an infusion of basic biomedical research, but adds that the ABRC does not favour a single national centre, preferring a "distributed approach" with "phased developments" at a number of provincial centres. Phillips concludes that this programme would cost "significantly less" than the single-centre option.

MacGregor said he was "naturally pleased" that the ABRC's preference on merit was for the cheaper approach. Dr James Scott, of the CRC, said the MRC had "gone for the stars" in asking for backing in the national research centre initiative and that it should not be too disappointed that it had not got complete support. He said the CRC had not been the success it should have been and that clinical research needed to "pull its socks up". Ben Webb

AIDS

AZT for children in extended US trial

Washington

THE US Food and Drug Administration (FDA) last week approved the use of the anti-AIDS drug AZT (zidovudine) to treat children.

Under the terms of a treatment IND (investigational new drug) programme, AZT will be provided free of charge by its manufacturer, Burroughs Wellcome, not only for children showing symptoms of AIDS but also for those lacking symptoms but in the advanced stages of infection with HIV (human immunodeficiency virus).

Two months ago, on the basis of trial results demonstrating that AZT slowed the progress of HIV infection, the drug was made available to asymptomatic but infected adults as well as those with overt AIDS. The new extension is also based on trial results: a study of more than 200 children has shown that AZT can both relieve symptoms and prolong survival. What had held back use of the drug for children was the fear that side-effects could be more severe in children than in adults, but the study results so far indicate that side-effects are not qualitatively different in children. David Lindley

For unto him that hath . . .

Virginia Trimble

The concept of P-selection, by which graduates of the more prestigious (P) universities tend to publish longer than those from other (NP) universities, is herewith introduced into the literature.

If you really want a career in scientific research, then get your PhD from the most prestigious university that will take you. This conclusion (which should surprise very few) follows from data collected for the Astronomy and Astrophysics Survey Committee, now in the process of preparing a report to the US National Academy of Sciences on Astronomy and Astrophysics for the 1990s.

To be precise, astronomers who received their doctoral degrees from a university that ranks repeatedly among the 'top three' American astronomical PhD programmes[1] continue to publish in the field about twice as long as those with degrees from a university that ranks in the 'second ten'. In addition, they are about twice as likely to have current jobs that primarily involve research and/or advanced teaching at observatories or PhD-granting universities.

One can imagine a variety of reasons for the difference. The more prestigious institution may genuinely provide a better education, or it may skim the cream from the available pool of entering students. Or its name may serve as a lubricant to smooth the paths to research grants, acceptance of papers and good jobs for its alumni, at least early in their careers. The data say nothing whatever about the relative importance of these or other causes for the phenomenon, though I am privately of the opinion that the third factor is not negligible.

The sample populations include 106 recipients of PhDs between 1952 and 1988 from the high-ranking institution (hereafter P) and 94 recipients of PhDs between 1966 and 1988 from the lower-ranking one (NP hereafter). Figure 1 shows their publication histories. The horizontal axis is number of years since receipt of doctoral degree. The vertical axis is the fraction of all astronomers who had had their degrees for at least *N* years who were still publishing papers listed in the semi-annual issues of *Astronomy and Astrophysics Abstracts*[2] at least *N* years after their degrees. Upper points pertain to P and lower ones to NP, and the differences are large enough to require no words to guide the eye.

The doctoral programme at P is the older one, and it might be hypothesized that the difference shown in Fig. 1 is a result of good jobs being easier to get in the past (back when our towers were made of real ivory rather than plastic and all our students were above average). As a test of this hypothesis, Fig. 2 shows the publication histories of post-1966 degree recipients from the two universities (85 from P, 94 from NP). Indeed the difference between the two is smaller than in Fig. 1, but the P astronomers are still about twice as likely to continue to publish for more than 18 years (when both samples drop below 10 members) than are the NP ones.

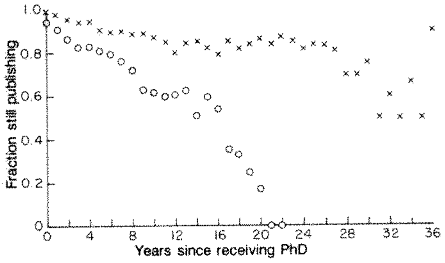


FIG. 1 Fraction of astronomers who have held PhDs for at least *N* years who are still publishing research papers *N* years after their degrees. Upper points = people from the prestigious university, P; lower points = people from the non-prestigious university, NP. Neither set of points starts out a unity because a few people from each place never published anything. Numbers drop below 10 people at 18 years for NP and 28 years for P.

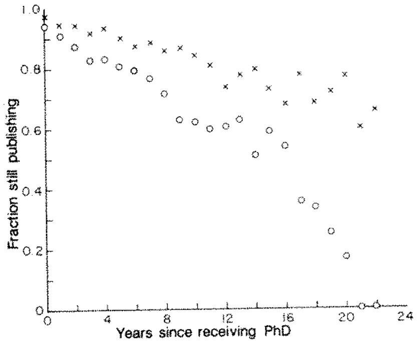

FIG. 2 Fraction of post-1966 degree recipients who are still publishing in astronomy as a function of number of years since the PhD. Upper points = P alumni; lower points = NP alumni. Numbers drop below 10 people between 18 and 19 years post-PhD for both.

Current employment patterns of the two groups are also significantly different. There are members of each group in each of nine categories: (1) astronomy research and teaching at observatories and PhD-granting universities; (2) astronomy research at government and industrial laboratories (like Los Alamos National Laboratory and AT&T Bell Laboratories); (3) research in other sciences; (4) scientific support services (data processing, hardware and software development); (5) industrial employment; (6) government employment (generally science administration); (7) teaching at places with no PhD programme in astronomy; (8) employment outside science; and (9) lost to follow-up and not publishing in astronomy (two from P, three from NP).

The most striking difference is that 65 per cent of the P astronomers, but only 32 per cent of the NP ones, have jobs in category 1. A large majority of incoming graduate students at both places describe their career goals as research and advanced teaching in the field. Most graduate programmes concur that their primary purpose is the production of the next generation of researchers. Thus the P astronomers can be described as more successful than the NP ones by their own standards.

Life being somehow easier in the past is not the primary cause. An artificial sample of P astronomers, age-matched to the NP ones, has 66 per cent of its members in the most desirable category of employment, just the same as for the total P sample. Curiously, this does mean that things are getting worse. People continue to diffuse out of the astronomical research community over their entire careers. But they almost never come back (though there is diffusion into the field of PhDs from physics and other sciences). No one in either sample resumed publishing after a hiatus of as long as five years. And the few returns to jobs in categories 1 and 2 occurred only when the excursions had been brief ones to positions in science administration. Thus we can expect that, 10 or 20 years from now, the fraction of the 1966–88 P astronomers still in research and advanced teaching will be less than 65 per cent and so smaller than the fraction of the total P sample now engaged in these activities.

The moral of the story is thus two-fold: it still pays to go to the most prestigious graduate institution you possibly can, but the gold paving, even on the streets of P, is not as thick as it used to be. □

Criminalization of drugs

Sir—Your leading article "Bush declares war on drugs" (*Nature* **341**, 1; 1989) is right in noting that if drug-related crime is to be totally eliminated, all drugs would have to be decriminalized, but it must be hoped that neither the United States, nor any other country for that matter, ends up decriminalizing narcotics or illicit drug use altogether.

You ask "would not a society in which narcotics were accessible that did not destroy itself by addiction be a stronger society and perhaps even kinder and gentler as well?". Problem drug-users have frequently told me, in the ten years in which I have worked with them, that "heroin blanks you out, it makes you emotionally distant". Many other drugs have even nastier and more antisocial effects. In the affluent West, the desire to achieve self-realization is common. Unfortunately, because of large-scale pharmaceutical drug use, it has become a drug-focused society. To be realistic, heroin and other euphoric and mind-altering drugs, whose use can at first be pleasurable, would be used on a wide scale if they were easily accessible. Would we want large sections of the population wandering around emotionally isolated and cut off from meaningful relations with others? Such a society would hardly be "kinder or gentler".

Clearly some degree of criminalization is necessary. But what is needed is a sensible policy suited to the real needs of containing the drug problem. For example, heroin, cocaine and crack are this decade's fashion. Designer drugs will be the major threat in the future. Should there not be international laws outlawing and controlling the illicit manufacturing of all synthetic drugs before they become a fashion?

Further, the British did not, as the author claimed, give up prescribing narcotics some 20 years ago because of the over-prescribing of one doctor. Rather, in the 15 years after the drug dependency clinics were set up in 1968, their consultant psychiatrist directors generally found that such long-term prescribing was medically harmful. Also, it generally did not help addicts to lead normal lives or keep them from crime. Even so, a small number of doctors continued to maintain addicts. Recently, in a move to combat AIDS, their numbers have increased. Most, however, offer only short-term treatment with reducing doses and aim to wean their patients off drugs as soon as possible.

Liberal prescribers such as Trebach argue that the British system of treatment was the reason why, until the 1970s, Britain had only a small drug problem. But, as I have indicated elsewhere, it was precisely because numbers were small that such a policy could be pursued. When the size of the addict population rapidly escalated in the 1980s, treatment and prescribing policies were ineffective in controlling the size of the addict population because heroin was cheap and easily available on the street. While illicit drugs remain easily available on the street, many of the addict population will, for a number of reasons, prefer not to seek maintenance prescriptions, but seek to buy illicitly — if for example, they are only recreational users, or they hate authority and the restrictions imposed by drug dependency units or prefer the excitement of the illegal subculture. And the drug market is organized in so complex a way that it would stimulate a demand on the street for their pharmaceutical drugs. Instead, large-scale liberal prescribing would increase the size of the illicit market, for it would lead to an extensive pharmaceutical blackmarket fed from the overspill from liberal prescribing.

It would be a very foolish policy-maker indeed nowadays who confused 'treatment' with drug control policy or containment.

Collision course

Sir—The race between the Stanford Linear Collider and the Large Electron–Positron Collider at CERN, the high-energy physics laboratory near Geneva, to be the first to elucidate the properties of the Z^0 particle raises fundamental questions about the purpose of particular scientific research projects in an era of increasing costs and declining resources. It was known from the beginning that the CERN machine would be able to produce Z^0s in much larger numbers than the Stanford machine. Thus, there was never an expectation that Stanford could produce data that would not eventually be available from CERN. The only question was whether Stanford could produce some of these data first. If some properties of the Z^0 had become known a few months earlier because of the Stanford experiment, it would have had absolutely no effect on scientific progress. It would, however, have been of significant advantage to the careers and reputations of the scientists involved in the Stanford experiment.

When the cost of a single machine such as the Superconducting Super Collider can approach the gross national product of a small developing country, we should question whether the taxpayers should be continuously called upon to support this kind of pointless competition and duplication of effort. If CERN, the United States, the Soviet Union and Japan cannot get together to fund and build a single high-energy physics machine, we should at least try to ensure that expensive facilities in one country complement rather than duplicate the capabilities of machines available elsewhere.

Stanford scandal

Sir—Dr Donald Kennedy (*Nature* **341**, 180; 1989) was not president of Stanford University at the time of the assault on Professor Leonard Hayflick, to which I alluded in a review — he was, I believe, head of the Food and Drug Administration in Washington — but the affair caused an international scandal, and unawareness among faculty members, even those who were not physically present, implies the lack of academic solidarity of which I complained.

I think that if Kennedy reviews the history of this affair, he will find my comments neither unjust nor intemperate.

Six of one . . .

Sir—Although one instinctively feels that all information is of value, the data quoted in your recent News and Views comment (*Nature* **341**, 181; 1989) on the British National Survey of Sexual Attitudes and Lifestyles suggest that Mrs Thatcher was right to doubt its value.

You quote the results of a preliminary survey as showing the average (lifetime) number of heterosexual partners as 11.0 for men and 2.9 for women. These figures are literally impossible. A heterosexual union is analagous to a heteronuclear chemical bond, and the total number must be the same if viewed from the male or female end. Thus the average numbers of partners must obey a 'bond consistency' condition

$$c_M N_{MF} = c_F N_{FM}$$

where c is a concentration and N_{MF} the number of female partners per male. Because by empirical observation the concentrations of males and females in the United Kingdom are the same, so must the average number of partners be. The survey results are clearly biased: probably both sexes bias their replies ("lie") in socially acceptable directions. The sociologist you quote was clearly right to be sceptical.

Water – the perfect medium for DNA replication

Autogene is the new water bath from Grant for rapid temperature cycling.

Rather than dry heat, it uses water – because this is the perfect medium for heat exchange. Water warms and cools rapidly and evenly because it completely surrounds anything immersed in it. This allows the rapid and efficient heat transfer which is so important in DNA replication.

Autogene has been developed from Grant's considerable experience in modern water bath technology. It is therefore backed up by Grant's traditional commitment to quality and reliability which means the extra peace of mind of a three year guarantee.

Autogene is flexible and versatile, and benefits from the following features:

- Temperature range 0°C to 99°C
- Maximum heating rate 1°C/2.5 seconds
- Maximum cooling rate 1°C/3 seconds
- Uniformity of temperature ± 1°C
- Max hold time 99.9 minutes
- Tap water/refrigerated cooling
- Holds different tube sizes and microtitre plates

Grant has a worldwide network of distributors, so wherever you are contact us today for more information.

IL-6 ELISA Kit
A search made simpler.

The InterTest-6™ ELISA kit offers you a simpler method of measuring human Interleukin-6 (IL-6). For studying the role of IL-6 in the immune response, inflammation, or cancers, the InterTest-6 kit gives you everything you need and more:

Sensitivity: accurate IL-6 measurements in the range of 0.5–25 ng/ml.

Specificity: no detectable cross reaction with TNF-α, IFN-γ, IL-1, IL-2, IL-3, IL-4, G-CSF, M-CSF, or GM-CSF.

Time savings: results are ready within 24 hours—three times faster than bioassays.

Convenience: contains all necessary reagents including microtiter strip wells and easy-to-follow instructions.

InterTest-6 is the newest addition to Genzyme's innovative line of immunoassay kits for research use. And, like all of our cytokine products, it comes with technical support and our guarantee of performance. For more information or to place an order, call **1-800-332-1042** or outside the USA **1-617-876-9404.**

IL-6 Production in Cell Cultures as Determined Using InterTest-6

Cell Culture	Duration	IL-6 ng/ml
T-cell clone 1	24 hrs	<0.3
T-cell clone 2	24 hrs	1.2
Transformed T-cell line	24 hrs	21.1
Plastic Adherent Cells + LPS	8 hrs	10.6
PBMC + PHA	24 hrs	4.9
PBMC + PHA	72 hrs	16.2
PBMC + Media	72 hrs	<0.3

Mechanical energy from light

In principle, it should be possible to turn radiation directly into mechanical energy, but the best designs so far of machines for doing this consist of paper studies. Somebody should build one.

LIKE mixing chalk and cheese, it grates on expectations of what the natural world is like to be asked to convert light energy directly into mechanical energy, to use sunlight for driving the transmission of a motor-car, for example. Despite present interest in what are called 'renewables', ecospeak for sources of energy alternatives to fossil fuels and uranium, the question is hardly ever asked. And if it were, the answer would almost certainly be a reference to well-tried space technology: make electricity first, and use that to drive the machine.

But that is too cowardly an answer. There is a direct conversion route, even a way of making light drive a piston along a cylinder, as in an internal combustion engine. What can that be? At this point, one must bury the thought that the explanation has to do with the Poynting effect, or with the well-attested truth that photons carry momentum and thus exert a force on whatever absorbs them. Toy radiometers are familiar enough; their aluminium sails do indeed spin round when exposed to light, but few would expect them to do much more — drive a motor-car, for example.

The true design of a light engine proceeds differently, beginning with a working fluid capable of absorbing light and behaving differently as a consequence. Suppose, for example, that one chooses a coloured gas, say a halogen vapour, and exposes that to sunlight. Energy will be absorbed and converted into heat, so that the pressure will increase. In a suitable arrangement, in a cylinder fitted with a piston for example, a modicum of work could be extracted. But the rate at which energy could be extracted from such a device — technically, its power — would necessarily be limited by the speed with which the working fluid could be restored to its condition at the beginnning of the cycle, and thus by the rate at which energy is lost by heat transfer to the surrounding medium. Nobody would expect even that to be enough to drive a motor-car.

Is there some way of augmenting that effect? This is the goal at which the designers of the light engine have set their caps. This is how the argument might go (as rehearsed as early as 1973 by A. Nitzan and J. Ross, *J. Chem. Phys.* **59**, 241; 1973). The trick is to choose as a working fluid a chemical species which is an efficient absorber of radiation, but which is itself replenished whenever its effectiveness as an absorber has been neutralized by having absorbed a photon, so that it is in an excited state.

Specifically, call the absorbing species A and the excited species A*. Suppose that A is itself a dissociation product of another chemical species B, that equilibrium is reasonably well satisfied between the species under the conditions in which the light engine functions and that the reaction by which B is converted into its components (including A) is endothermic. That would mean that, if the temperature increased, there would be more of the product (A*) in the absorbing gas, which would imply positive feedback. One could hope to keep the process of light-absorption going not for milliseconds but for tenths of a second or thereabouts.

That is the point at which three members of the department of chemistry at the University of Chicago get down to business. S. J. Watowich, K. H. Hoffman and R. S. Berry (*Il Nuovo Cimento* **104B**, 131; 1989) choose as their working fluid the fluorosulphate free radical — stoichiometrically SO_3F, which is nothing but SO_4 in which one O has been replaced by an F. But SO_3F has the interesting property of forming dimers that are neither free radicals nor absorbers of radiation; $S_2O_6F_2$ is simply a reservoir from which absorbing gas can be regenerated whenever there is a tendency for the temperature to increase.

In simple terms, the consequence is chiefly to increase the duty cycle of a light engine based on a light-absorbing molecular gas. But the increase may in principle be very great. If A* is not fluorescent, energy from the excited molecule can escape only by means of molecular vibrational modes, a process of thermal degradation which both restores the original absorbing molecule and which must separately increase the concentration of the absorbing species by shifting the chemical equilibrium.

How to make a light-driven mechanical engine from those ingredients? Watowich *et al.* do their best. Implicitly, they acknowledge that, in the construction of a novel energy-transducer, what matters is not theoretical efficiency but power output per unit of mechanical engineering effort. For that reason, their design study ends up with SO_3F embedded in more than 1,000 times as much buffer gas, perhaps molecular nitrogen (to increase heat conduction and thus reduce the length of the duty cycle). A large part of the trick is to operate the light engine in a condition in which the working fluid is metastable — endowed with a greater potential than would be found at equilibrium to replenish stocks of SO_3 depleted by the absorption of radiation.

Several difficulties underlie their calculation, at least one of which is philosophical. Ehrenfest's law of detailed balancing implies that, if one can define a molecular species of any kind, one can, in a steady state, equate the total rate at which it is created with that at which it is destroyed. But Ehrenfest was innocent of quantum mechanics, and would not have worried much about the possibility that a dimer in equilibrium with its monomer in the presence of excited versions of the latter might not behave as if the old-fashioned law of mass action were universally applicable. Ordinarily, of course, he would have been on sure ground.

But the mechanical light-engine requires that the conversion of dimer into monomer molecules should be so much more rapid than the rate at which excited monomers lose energy through conversion to intramolecular vibration, and thus enhanced collision frequency, that excited and non-excited monomer states are never confounded. That is probably a mistaken supposition in circumstances in which the effectiveness of the light engine depends on the speed at which the duty cycle can be completed.

These are strictly theoretical objections, of course. They could be answered simply and conclusively by a demonstration that it is possible to build a machine, with some working fluid or other, that will drive a flywheel when it is exposed to a light, perhaps one more intense than sunlight. Sadly, this seems not to have been done. In the tradition of *Il Nuovo Cimento*, Watowich *et al.* hew to the principle that a gram of theory counts for a tonne of experiment, and is usually easier. For what it is worth, the paper efficiency of a working machine turns out to exceed 0.25, just a little greater than that of the best amorphous silicon converters of solar energy into electricity. But it would be more than just fun if somebody were to build one, even a much less efficient version. Then, at least, there would be a tangible incentive to improve on paper performance.

John Maddox

CELL BIOLOGY

The cell cycle as a *cdc2* cycle

Andrew W. Murray

ORDERLY cell division depends on the coordination of the events of the cell cycle. In eukaryotes this coordination is produced by the regulation of three cell cycle transitions: entry into mitosis, exit from mitosis, and passage through a point in G1 named Start, that commits the cell to initiating DNA synthesis (the S phase). It is now believed that in all eukaryotes each of these transitions is regulated by controlling the activity of a single protein, pp34 — the product of the *cdc2* gene. A model of the cell cycle as a series of closely regulated changes in the activity of pp34 is shown in the figure. On page 39 of this issue[1] Gould and Nurse show that one of these changes is the dephosphorylation of a single tyrosine residue on pp34 and that this reaction facilitates entry into mitosis.

Originally identified as the product of the *cdc2* gene of the fission yeast *Schizosaccharomyces pombe* and the *CDC28* gene in the budding yeast *Saccharomyces cerevisiae*, pp34 is now known to be the catalytic subunit of the mitosis-inducing protein kinase known as maturation promoting factor (MPF) or growth-associated H1 kinase (see ref. 2). The other major subunits of MPF are the cyclins[3-7], proteins that accumulate in each interphase and are degraded at the end of each mitosis (reviewed in ref. 8).

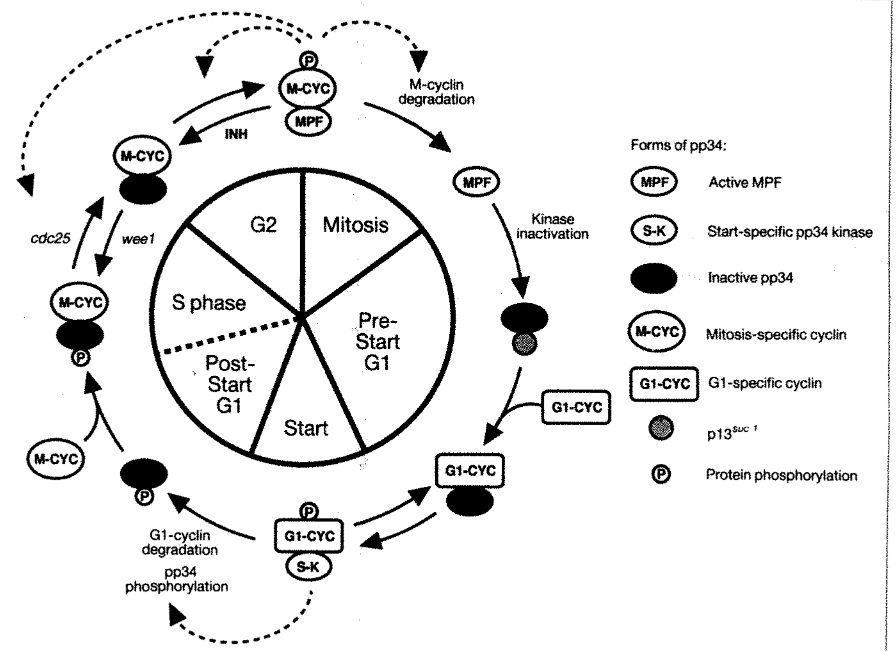
Fission yeast requires *cdc2* activity both for passage through Start and for the induction of mitosis. In this organism, entry into mitosis is controlled by the ratio of the activity of two genes: *cdc25*, which stimulates entry into mitosis, and *wee1*, which inhibits it and has homology to known protein kinases[9]. In late interphase pp34 is phosphorylated on both threonine and tyrosine[10]. The activation of MPF, both *in vivo* and *in vitro*, is accompanied by dephosphorylation of both amino acids[11-14], leading to the idea that the dephosphorylation of pp34 regulates the activation of MPF. Gould and Nurse's new data from fission yeast strongly support this hypothesis.

Their findings can be summarized as follows. In fission yeast whose cell cycle has been arrested in G2 by a temperature-sensitive *cdc25* mutant, pp34 is phosphorylated on tyrosine 15 and on an unidentified threonine. When the cells are returned to the permissive temperature the abundance of both phosphoamino acids declines and the cells enter mitosis. When phenylalanine is substituted for tyrosine 15 of pp34, the mutant protein is no longer a substrate for tyrosine phosphorylation. Strains that carry this mutation grow poorly, even though they divide at a much smaller size than wild-type cells. Moreover, they exhibit a large number of aberrant cell divisions that are presumed to result from premature entry into mitosis. (This phenotype is strongly reminiscent of the 'mitotic catastrophe' induced by the over-expression of *cdc25* in strains carrying mutations in *wee1* (ref. 15).) Finally, the mutant strain can still exit from mitosis, demonstrating that tyrosine phosphorylation of pp34 is not required for this step.

These elegant experiments suggest that the antagonistic effects of *wee1* and *cdc25* may act to control the tyrosine phosphorylation of pp34. This mechanism for controlling entry into mitosis is probably phylogenetically conserved, as homologues of *cdc25* have been found in *Drosophila*[16] and *S. cerevisiae*[17]. Unfortunately, the simplest scheme — that the *wee1* product is the pp34 tyrosine kinase and the *cdc25* product is the pp34 tyrosine phosphatase — is unlikely to be true for several reasons. First, the sequence of the *wee1* product resemble serine/threonine kinases rather than tyrosine kinases. Second, the sequence of the *cdc25* product does not resemble known protein phosphatases. Finally, the dramatic effect of overexpressing *cdc25* in strains mutant for *wee1* (ref. 15) shows that *cdc25* must do more than simply reverse the inhibitory effects of *wee1*. It will clearly be of interest to determine whether *wee1* activity is required for the tyrosine phosphorylation of pp34 and the effect of mutating the sites of threonine phosphorylation on pp34. The ability of fission yeast to divide normally in the absence of both *cdc25* and *wee1* functions[9] indicates that there are additional controls on the activation of MPF that remain to be discovered.

How many biochemical steps are involved in activating the mitosis-specific activity of pp34? Two that we know of are cyclin accumulation[18,19] and pp34 dephosphorylation[1, 11-14]. In addition, in sea urchins an increase in cyclin phosphorylation parallels the activation of MPF[7]. Thus, in the illustrated model, cyclin (M-CYC) binding to pp34 is required to allow the removal of tyrosine and threonine phosphates from pp34, and the subsequent phosphorylation of cyclin that yields active MPF. The level of phosphorylation of pp34 and cyclin is determined by the balance between kinases and phosphatase activities, so many different regulatory signals can act on this part of the cycle. The *cdc25* and *wee1* genes are shown as stimulating, respectively, the dephosphorylation and phosphorylation of pp34.

In the model, the dephosphorylation of cyclin is mediated by INH, an inhibitor of MPF activation that has been postulated to be a phosphatase[20]. MPF catalyses the activation of inactive forms of MPF[1,12,20] and the incorporation of phosphate into the cyclin component of MPF[4,5,7], indicating that it may be the physiological cyclin kinase. The model also shows MPF acting indirectly to increase the rate of tyrosine dephosphorylation. These autocatalytic steps would ensure that the rise in the levels of MPF is rapid and not easily



A model of the cycle of pp34 (outer ring) during the cell cycle. The pp34 molecule lacks kinase activity during most of the cell cycle but becomes active as MPF at mitosis and as a Start-specific kinase at Start as a result of association with phosphorylated cyclins. Note that the active forms can also stimulate their own activation and/or inactivation (----▶). The dashed line between post-Start G1 and S phases indicates that no change in pp34 accompanies the onset of replication.

reversible. It is not known whether pp34 dephosphorylation requires cyclin accumulation or pp34 activity, but this question can be addressed experimentally in both intact fission yeast and frog egg extracts.

How is MPF turned off at the end of mitosis? Cyclin degradation is necessary for the exit from mitosis[21], but the existence of cyclin-free forms of MPF *in vitro*[12], and the transient existence of H1 kinase activity after the destruction of cyclin *in vivo*[22], suggest that cyclin degradation is not sufficient for the inactivation of MPF. One candidate member of the inactivation pathway is p13^{suc1}, the product of the fission yeast *suc1* gene. Not only are cells deleted for this gene unable to inactivate MPF[22], but the gene product binds pp34, stabilizes the kinase activity of certain temperature-sensitive alleles of *cdc2* (refs 5, 22), and can block the dephosphorylation of pp34 in frog extracts[14]. Perhaps, in the absence of cyclin, p13^{suc1} binding to pp34 destroys the catalytically active conformation of the molecule or renders it a substrate for some inactivating activity. In both *Aspergillus* and fission yeast, mutants in type 1 phosphatase genes are defective in the exit from mitosis (see ref. 23). It is not yet known whether the defect in these strains is in the inactivation of MPF or in the removal of phosphate from molecules whose phosphorylation is induced by active MPF.

In mammalian cells and budding yeast, Start is the point in the cell cycle where cells monitor cell size and nutrient availability. What role does pp34 play in this cell-cycle transition? Recent evidence from the fission yeast[24-26] suggests there are G1-specific cyclins (G1-CYC in the model) that activate a Start-specific protein kinase activity of pp34 in much the same way as the mitosis-specific cyclins activate MPF. The mechanisms that regulate Start, the biochemical events that are the manifestation of passage through Start, and the substrates of the Start-specific activity of pp34 are mostly unknown. In exponentially growing HeLa cells, the level of phosphotyrosine in pp34 does not increase until the onset of S phase[11]. This observation raises the possibility that tyrosine phosphorylation of pp34 is a consequence of passage through Start and requires the Start-specific activity of *cdc2*, just as the tyrosine dephosphorylation at mitosis is postulated to require the mitosis-specific activity of *cdc2*. Thus, tyrosine phosphorylation of pp34 would serve as a marker for those cells that had passed through Start, as well as regulating entry into mitosis.

If complete removal of pp34 phosphotyrosine is dependent on high levels of MPF activity this stigma of passage through Start could not be removed without entry into mitosis. Such a scheme provides a biochemical means for the cell to remember where it is in the cell cycle and thus ensure a regular alternation of Start and mitosis. Finally, if the removal of phosphotyrosine from pp34 is dependent on the completion of DNA synthesis, mitosis could not start until DNA synthesis had finished. ☐

ATMOSPHERIC CIRCULATION

Variations without forcing

Marvin A. Geller

ATMOSPHERIC conditions can vary over a vast spectrum of timescales — extending up to the Milankovic cycles operating over millenia and forced by variations in the Earth's orbit. But James and James warn on page 53 of this issue[1] against reading too much into correlations between climate cycles and the periods of plausible forcing mechanisms. In particular, they show that one 11-year circulation cycle that appears to be related to the 11-year solar cycle[2] can arise naturally from the internal dynamics of the atmosphere.

James and James base their warning on computer simulations of the climate for timescales of 100 years. The physical inputs of the simulation were deliberately simplified to facilitate the long integration times, but included steady solar heating, the effects of friction on the atmospheric circulation, effects due to the Earth's rotation and, in one case, the seasonal cycle. Other variations in external forcing are deliberately excluded. The important difference from previous simulations is the allowance for nonlinear effects in such long integrations.

The resulting atmospheric circulation was examined for periodic variations. This is best illustrated in the spectra in Figs 2–4, on pages 54–55 of this issue, which show the variation of a particular parameter of the circulation — the (0,1) vorticity coefficient which reflects the excess of atmospheric rotation over the Earth's. Despite the lack of any long-period forcing, the circulation varies strongly for periods longer than a year, the strongest response being at around ten years. This is apparent in the simulations that include annual forcing (Figs 2 and 3) and, most significantly, in the simulation in which this was excluded (Fig. 4). This demonstrates, James and James conclude, that the presence of decadal variations in the atmosphere does not imply that a forcing mechanism of similar period is at work, a conclusion anticipated in long-term simulations of temperature changes from a general circulation model[3].

The new results imply that this type of variability can occur as a result of long-lived, non-random effects in the nonlinear atmospheric flow. Unlike linear systems, nonlinear systems can respond to internal and external forcings over periods much longer than those directly being forced. The results of James and James suggest that, although the internal atmospheric instabilities generate internal variability in the fluid flow on timescales of the order of ten days, these are organized by the nonlinear flow into long-lived structures that show variations over timescales as great as ten years: the decadal variations are internally produced.

This result is very relevant to suggestions of a connection between climate and the solar cycle. Two years ago, Labitzke and van Loon[2] published a provocative paper demonstrating excellent correlation between atmospheric variability at stratospheric levels during the winter months and solar activity. This becomes apparent when the winter data are subdivided into two sets according to the phase of the quasibiennial oscillation (QBO) in the lower-stratospheric tropical wind patterns. The authors have since demonstrated that these strong correlations also exist at tropospheric levels and during other seasons[4,5].

There have been several attempts to check the validity of Labitzke and van Loon's statistical approaches. In most cases, their procedures are considered to have passed these tests. In fact, the statistical associations have been sufficiently convincing that some operational forecasts of seasonal mean climate have begun to use the results in making these forecasts[6]. At the same time, strong scepticism has also been expressed about the idea that the correlations imply that solar activity controls the lower atmosphere. The results of the James and James paper provide a good perspective in which to examine this situation.

Van Loon and Labitzke[4] state the issue very well at the end of their paper:

> Some of our colleagues have suggested that what we have detected is a strong tendency for large-amplitude atmospheric variability on a decadal timescale which shows when the observations are filtered through the Quasi-Biennial Oscillation. This is of course a possibility, but such variability has no obvious explanation either. We find it remarkable if an internal oscillation in the atmosphere on a decadal time scale happened to be in phase with the 11-year solar cycle during the very 36 years when we describe it.

James and James clearly do suggest an explanation for atmospheric variability on a decadal timescale: it occurs as a consequence of internal variability. Although it may be improbable that the phase of this internal mode of variability coincides with the phase of solar variability, it is not wildly so. Given that the periods of both variations are about ten years, the probability that they appear to be in phase is about one in five. Furthermore, as both variations tend to be coherent over several cycles, once they are in phase with one another they will tend to stay in phase for several cycles.

The conclusion that Labitzke and van Loon's work implies a large atmospheric response to solar activity forcing has been criticized[7,8] from two additional perspectives. Baldwin and Dunkerton[7] have subjected atmospheric data to the same statistical procedure except they correlate them with simulated harmonics of arbitrary period instead of the solar cycle. They find that correlations equal to or even exceeding those found by Labitzke and van Loon between atmospheric variations and solar activity occur in approximately 5 per cent of these cases. Again, the point is that, viewed over a short number of periods, there is a small but reasonable probability of finding phase matching between two unconnected cycles. This is the flaw in concluding that Labitzke and van Loon's correlations are forced by solar activity.

Barnett[8] shows that there is a significant quasi-biennial variation in tropical sea-surface temperatures, the amplitude of which is modulated over a ten-year period, apparently in phase with the solar cycle. One possibility is that there is a causal relationship between solar variability and the ocean. Or perhaps the decadal atmospheric variability indicated by James and James's results forces the ocean variations. Or the atmosphere and ocean together may display modes of variability that are not present in either individually[9]. Thus, the atmosphere–ocean system has many ways of producing decadal variations internally.

No physical mechanism capable of quantitatively explaining any effect of solar activity on the lower atmosphere has been identified, despite many years of research: this is because solar activity can modulate only weakly the energy put into the atmosphere. Without a plausible mechanism, it is much more likely that we are seeing physically unrelated, though correlated, internal variations in the Sun and internal variations in the atmosphere or ocean–atmosphere system. ☐

CALCIUM SIGNALLING

Receptor kinships revealed

Donald L. Gill

JUST six years have passed since the action of inositol 1,4,5-trisphosphate (InsP$_3$) on the release of intracellular Ca^{2+} was first reported[1]. Since then InsP$_3$ has become recognized as a universal 'second messenger' that is released into the cell cytosol following the breakdown of phosphatidylinositol 4,5-bisphosphate in response to cell surface receptor-mediated activation of phospholipase C. InsP$_3$ is then either further metabolized (see ref. 2) or it interacts with the receptors that mediate intracellular Ca^{2+} release, but whose nature has remained obscure. Recently, Supattapone *et al.*[3] isolated an InsP$_3$-binding protein from the cerebellum that had properties consistent with the receptor. Now an ensemble of independent reports from the laboratories of Mikoshiba[4], Snyder[5] (on pages 32 and 87 of this issue) and Südhof[6], provide important sequence and structural information on this protein and compelling evidence that the same molecule mediates both InsP$_3$-binding and the release of Ca^{2+} from the endoplasmic reticulum. Surprisingly, the structure of the InsP$_3$ receptor is also shown to be strikingly similar to the recently cloned ryanodine receptor (RR)[7], the Ca^{2+} channel of the sarcoplasmic reticulum of skeletal muscle.

An interesting history precedes identification of the InsP$_3$ receptor; the same protein has been described independently several times from as early as 1976 (see refs 4 and 5). The extraordinary abundance of the protein in cerebellar Purkinje cells provides an explanation for this unusual degree of attention. It is a membrane glycoprotein with a relative molecular mass (M_r) of 250,000 (250K) which binds to both heparin and concanavalin A (enabling an effective purification scheme[3]), and is a major substrate for cyclic AMP-dependent phosphorylation[8]. Various names have been assigned to the protein; Mikoshiba and colleagues refer to it as P$_{400}$ (based on a somewhat spurious original size determination), whereas it is also referred to as PCPP-260 (ref. 8) and GP-A (ref. 9). Henceforth, it seems we may now have confidence in referring to it as the functional InsP$_3$receptor (InsP$_3$R).

Furuichi *et al.*[4] in Mikoshiba's laboratory used three monoclonal antibodies to the purified P$_{400}$ protein to identify complementary DNAs within mouse cerebellum cDNA libraries that expressed the protein. Eventually, the entire cDNA sequence was obtained, revealing an open reading frame encoding a protein of 2,749 amino acids of theoretical M_r 313K. From hydropathy profiles, the authors conclude that the protein contains up to nine membrane-spanning domains, but from immunolocalization studies not presented a very large N-terminal region of the protein is on the cytoplasmic face of the endoplasmic reticulum (ER), so that it is only a cluster of up to seven transmembrane domains close to the C terminus that is likely to exist. Localization of the C terminus on the luminal side of the ER was made possible by a nearby epitope and by evidence of glycosylation in the same region. The large cytoplasmic domain probably contains the InsP$_3$ recognition site (and regulatory elements) with the transmembrane domains providing the Ca^{2+}-translocating region; however, assignment of functional domains is still tentative.

Quite independently, Mignery *et al.*[6] in Südhof's laboratory made several rather intuitive deductions. They noticed that the recently reported[10] partial sequence of a major Purkinje cell transcript named PCD6 (containing an open reading frame encoding 500 amino acids) was for a protein containing several transmembrane domains and perhaps, therefore, an abundant channel protein. With antibodies to the C-terminal peptide, Mignery

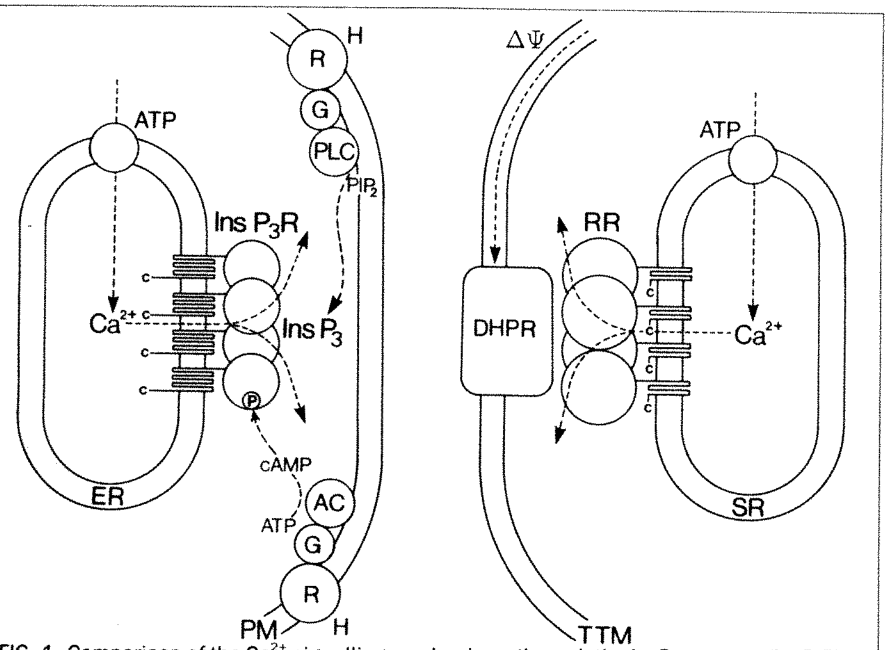

FIG. 1 Comparison of the Ca^{2+} signalling mechanisms through the $InsP_3$ receptor ($InsP_3R$) in nonmuscle tissue (left) and the ryanodine receptor (RR) in skeletal muscle (right). In nonmuscle, hormones (H) binding to plasma membrane (PM) receptors (R) coupled to G proteins (G) activate phospholipase C (PLC) and the breakdown of phosphatidylinositol 4,5-bisphosphate (PIP_2) to release inositol 1,4,5-trisphosphate ($InsP_3$) into the cytosol. The action of $InsP_3$ on Ca^{2+} release from endoplasmic reticulum (ER) is mediated by the $InsP_3R$, depicted here as being tetrameric (although of a size suggesting four molecules, the number of subunits in the $InsP_3R$ complex has not been determined). In addition, cAMP, produced by hormonal modification of adenylyl cyclase (AC), activates phosphorylation of the $InsP_3R$ and inhibits $InsP_3$-induced activation of Ca^{2+} release[19]. In skeletal muscle, the initial signal is an electrical depolarization ($\Delta\Psi$) of the T-tubule membrane (TTM), which is detected by the voltage-dependent dihydropyridine-sensitive receptor (DHPR). The signal is believed to be modulated by the RR N terminus (in close contact with the DHPR) into opening of a channel within the core of the RR tetrameric structure[7,11]. In both systems, the end result is Ca^{2+} release into the cytosol. Note that the C terminus (C) of the $InsP_3$ the is luminal, whereas that of the RR is believed to be cytoplasmic[7].

et al. rapidly identified the sequence as part of a heparin-binding protein, of M_r 260K, whose identity with the protein described by Supattapone *et al.*[3] was confirmed by its ability to bind $InsP_3$. Indeed, its 500-amino-acid sequence differs by only one amino acid from the C-terminal sequence obtained by Furuichi *et al.*[4].

Is this molecule the functional receptor or merely an $InsP_3$-binding constituent of a larger Ca^{2+}-releasing complex containing additional proteins? The answer is convincingly provided by Ferris *et al.*[5] in the Snyder laboratory, who have now demonstrated that the purified molecule, incorporated into liposomes, mediates Ca^{2+} release in response to $InsP_3$ concentrations that saturate the binding site. Perhaps most satisfying is the pharmacological specificity: Ins(1,3,4)P_3, a metabolite of Ins(1,4,5)P_3 with very little activity *in vivo*, is completely ineffective in inducing Ca^{2+} release in the reconstituted system. Although additional proteins are apparently not required for $InsP_3$-induced transport, evidence discussed below suggests that the functional receptor is a multimer of the protein now described.

It comes as a major revelation that the $InsP_3R$ and the RR have similar structures. Over a region of 134 amino acids (residues 2,541–2,674) in the C-terminal region of the $InsP_3R$ there is 46 per cent identity (64 per cent including conservative changes) with the C-terminal region of the RR. In both cases the region contains the final transmembrane domain. The adjacent transmembrane domains and smaller regions scattered throughout the large N-terminal region of the two molecules are also similar. The total number of possible transmembrane domains in the $InsP_3$ receptor is in some dispute. As opposed to the seven suggested by Furuichi *et al.*[4] (which account for oppositely orientated N and C termini), Mignery *et al.*[6] identify four (the same as the RR), but in either case they all occur within the last 475 C-terminal amino acids. Regardless of the number of transmembrane domains, the overall topology of the $InsP_3R$, including a large cytoplasmic N-terminal domain and transmembrane domains clustered close to the C terminus, closely resembles the RR, as shown in Fig. 1. However, the evidence suggests that the $InsP_3R$ C terminus is luminal (see above), whereas the RR C terminus is apparently cytoplasmic. Considering the structural similarity between the C termini and two adjacent membrane-spanning domains, it seems strange that the two regions should be oriented oppositely across the membrane, as it is likely that such regions have important functional correlates (for example, ion translocation).

Another important similarity between the $InsP_3R$ and the RR is that both associate into multimeric structures. There is agreement[3,4,6] that the M_r of solubilized $InsP_3R$ is around 1,000K, suggesting a tetrameric structure, as shown in Fig. 1. This is particularly reminiscent of the RR, which is believed to function in sarcoplasmic reticulum junctions as a tetramer in an approximately square configuration[11], the four subunits possibly surrounding a central Ca^{2+} channel. Indeed, Furuichi *et al.* refer to electron-microscopic evidence for the existence of just such a square-shaped multimeric structure for the $InsP_3R$. Moreover, a multimeric arrangement is indicated by certain functional studies. Thus, there is good evidence that $InsP_3$ receptors function cooperatively, occupancy of three or more sites contributing to channel opening[12]; also, the high antagonistic potency of oligomeric heparin (more than 5 nm in length) on $InsP_3$ effects could reflect a close proximity between groups of $InsP_3R$ molecules[13]. Further assessment of tertiary and quaternary structure of the $InsP_3R$ may reveal much more about the function and control of Ca^{2+} release.

What is the function of the very large N-terminal domain of the $InsP_3R$? By analogy (and limited sequence homology) to the N-terminal 'foot' of the RR, which is believed to interact with the dihydropyridine-sensitive receptor in fast muscle (Fig. 1), could this domain be involved in connections to another controlling

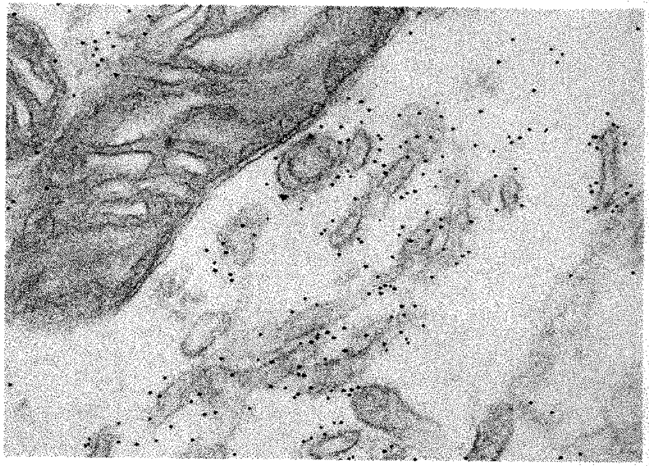

FIG. 2 Localization of the putative $InsP_3$ receptor in a cerebellar Purkinje cell. Electron micrograph of a cell treated with a gold-labelled antibody to a peptide of the receptor, shows that gold particles are confined to the endoplasmic reticulum. (From ref. 6.)

protein? The lack of any strict organizational configuration of InsP$_3$-responsive organelles, compared with the precise organization of sarcosplasmic reticulum feet, would militate against such a role. This raises the question of exactly where within cells InsP$_3$ receptors are localized. On this point the results are not so consistent. Recent immunocytochemical studies[14], show that the ER is a principal site of InsP$_3$R, particularly rough ER (and nuclear envelope), but also peripheral smooth ER (sometimes at locations close to the plasma membrane). The immunolocalization of Mignery *et al.*[6] is generally consistent with this, although showing more uniform ER labelling (Fig. 2). But Furuichi *et al.*[4] provide evidence for additional localization in the plasma membrane, a result that supports the functional data of Kuno and Gardner[15] for InsP$_3$R-mediated Ca^{2+} translocation across this membrane.

The interesting heterogeneity of InsP$_3$R locations does not support the idea of a single specialized InsP$_3$-responsive organelle (the calciosome) within cells as suggested by Volpe *et al.*[16]. We must also consider the occurrence of complex and dynamic interactions between InsP$_3$-sensitive and -insensitive organelles mediated by intracellular G proteins[17]; such changes may considerably alter the size and location of InsP$_3$-responsive Ca^{2+} pools, and hence the vicinity of InsP$_3$ receptors.

Lastly, we should consider that much of what has been discussed relates to Purkinje cells, where the massive InsP$_3$R density is apparently designed to facilitate extensive granule cell interactions, which are mediated by glutamate receptors coupled to phosphoinositide breakdown[18] (the cerebellum is thus almost a 'skeletal non-muscle' tissue in terms of specialized Ca^{2+} signalling). Whereas indentical InsP$_3$ receptors appear to exist in most other cell types (S.H. Snyder, personal communication), their organization, control, and distribution may be quite different. □

OCEAN DRILLING PROGRAM

Arc volcanism and rifting

*Leg 126 shipboard scientific party**

ACTIVE island-arc volcanoes, noted for their explosive eruptions, characterize the margins of converging oceanic plates. Our knowledge of the nature of volcanism and sedimentation in these areas, and how 'forearc' and 'backarc' basins are formed, has been significantly advanced by recent ocean drilling in the central Izu–Bonin Arc, south of Japan (Fig. 1). Our initial results show that arc rifting is geologically rapid, requiring only two to three million years, and can occur on either or both sides of the island arc. The rifting stage is accompanied by intense volcanism and rapid sedimentation, whereas during subsequent backarc spreading the arc may be relatively quiescent. Volcanism, even explosive eruption, is not restricted to the island arc, but may occur in deep water to either side.

The Izu–Bonin volcanic arc is a product of 50 million years (Myr) of subduction of Pacific lithosphere. Backarc spreading between 25 and 15 Myr ago in the Shikoku Basin separated the formerly contiguous Kyushu–Palau Ridge from the still active arc (Fig. 1). We drilled in the Sumisu Rift to investigate the geological processes associated with renewed rifting of the arc (before backarc spreading). We also drilled in the forearc basin and discovered that it, too, was formed by rifting, in the mid-Oligocene (28–31 Myr ago).

Four cycles of explosive volcanic activity in the last 250 thousand years deposited glassy and pumiceous silts, sands and gravels which we recovered at the Sumisu Rift sites 790 and 791. This material probably erupted from the nearby Sumisu and/or South Sumisu calderas. The pumiceous unit overlies nannofossil-rich clays, with thin ash beds and scattered pumice and scoria clasts, that date back to 1.1 Myr ago. Sedimentation rates increase exponentially from 80 and 300 m Myr^{-1} at 1 Myr ago to 1,000 and 2,250 m Myr^{-1} in the past 100 thousand years at sites 790 and 791, respectively. Benthic foraminifers are consistent with deposition in the present 2-km water depths during the past 730 thousand years and at somewhat deeper levels previously. These data require rapid, differential and accelerating subsidence and sedimentation in the rift half graben. In contrast, only about 30 m of pumiceous gravel have been deposited in the past 275 thousand years, above a major unconformity at the rift margin site 788. The unconformity is the result of margin uplift of between 200–1,700 m (according to benthic foraminiferal data) since the deposition of the underlying pumiceous units 2.35–3.56 Myr ago. The rift formed very quickly, beginning 2 ± 0.5 Myr ago.

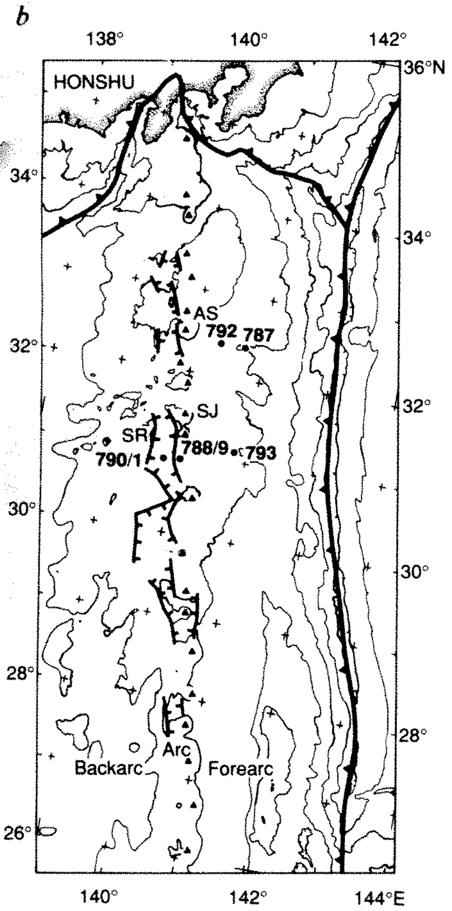
Thick barbed lines locate subduction zones and lines with tic marks indicate rifts. SR=Sumisu Rift; AS=Aoga Shima; SJ=Sumisu Jima. ▶

A 135-m-thick basalt unit at site 791 probably resulted from submarine fountaining of hydrous lava deeper than 1,500 m below sea level. This unit is composed of clastic basalt froth: both the glassy matrix and clasts are honeycombed with small vesicles, totalling 30–40 per cent porosity. All the tholeiitic basalts at sites 790 and 791 are highly vesicular (20–30 per cent), despite their eruption in deep water, owing to their high pre-eruption water contents. The rift basement basalts may be distinguished from Izu–Bonin arc basalts by their lower barium contents (below 30 parts per million) and higher TiO$_2$ contents (above 0.95 per cent) relative to MgO, zirconium and vanadium.



The basalts at site 791 have concentrations of barium and rubidium as low as those in mid-ocean ridge basalts and in the most mature backarc basins, indicating that basalts' compositions can lose their arc-like geochemical characteristics very early in the rifting stage of backarc basin development. The lowermost rocks at site 791 are arc-derived pyroclastics. Their pumice shards have a eutaxitic texture suggesting hot emplacement, but it is uncertain whether they were emplaced before or during rifting.

Intra-oceanic forearc basins have been avoided by previous drilling legs because of their large sediment thickness. Their stratigraphy, however, records the history of forearc sedimentation, arc volcanism, microstructural deformation and plate motion. To recover this record, and to sample the underlying basement for the first time, we drilled at three sites in the Izu–Bonin forearc (Fig. 2). Studying the basement at the centre of the basin involved drilling the Ocean Drilling Program's deepest hole yet (793B), to 1,682 m below the sea floor.

The three forearc sites documented a characteristic pattern of volcanogenic input: extremely rapid activity before 28 Myr ago; moderate between 28 and 24 Myr ago; minimal between 24 and 13 Myr ago; and moderate and increasingly fast from 13 Myr ago to the present. This pattern is similar to that observed previously at site 296 on the northern Kyushu–Palau remnant arc ridge (Fig. 1). The early and early-middle Miocene minimum in volcanism corresponds in time with the backarc opening of the Shikoku Basin. This interval is represented in the forearc by nannofossil-rich claystones and nannofossil chalks, quite unlike the surrounding turbidite sequences.

The 200 ash layers (or more) in the upper unit at site 792 are evidence of continuing explosive volcanism since 3 Myr ago. Together with the volcanic record from sites 788–791, they indicate that the Pliocene-to-recent pre- and synrift volcanism and sedimentation along the volcanic front is dominated by rhyolite pumice eruptions. There is no evidence during this time of igneous vents or lava flows between the central Izu–Bonin arc volcanoes, in contrast to arcs such as Japan and the Cascades.

Given the known presence of middle Eocene volcanic highs on both sides of the forearc basin, a big surprise was the lack of Eocene or mid- to lowest-Oligocene (45–34 Myr ago) sediments in the basin. At 715 m below sea floor at site 792, we penetrated an angular unconformity that underlies nearly all the north–central forearc basin sediments. The sediments below this unconformity and down to basement are biostratigraphically and magnetostratigraphically dated as younger than 34 Myr old. At site 793, in the centre of the south–central forearc basin, the sediments overlying the igneous basement are 31 Myr old. Clearly there was no basin before this time. We infer that the surrounding Eocene outer arc and frontal arc highs were formerly contiguous, and that the 40–70-km-wide forearc basin formed when they were separated by rifting in the mid-Oligocene. The stretching event probably affected the whole Eocene basement terrain, from the outer-arc high to the now-remnant arc ridge (site 296). The newly formed basin, 4–5 km deep according to benthic foraminiferal data, was rapidly (250–300 m Myr^{-1}) filled with turbidite and debris flow deposits, produced by both concurrent volcanism and erosion of the surrounding highs.

The basement at site 793 includes pillowed and massive lavas and more abundant hyaloclastite breccias. Most of the volcanics belong to a high-Mg series of basaltic andesites with boninitic affinities. Others belong to a low-Mg series with tholeiitic affinities. The basement high penetrated at site 792 may form the edge of one of the Eocene–Oligocene frontal arc highs which, like the volcanoes at the present volcanic front, are separated by 20–80 km. The basement lavas at site

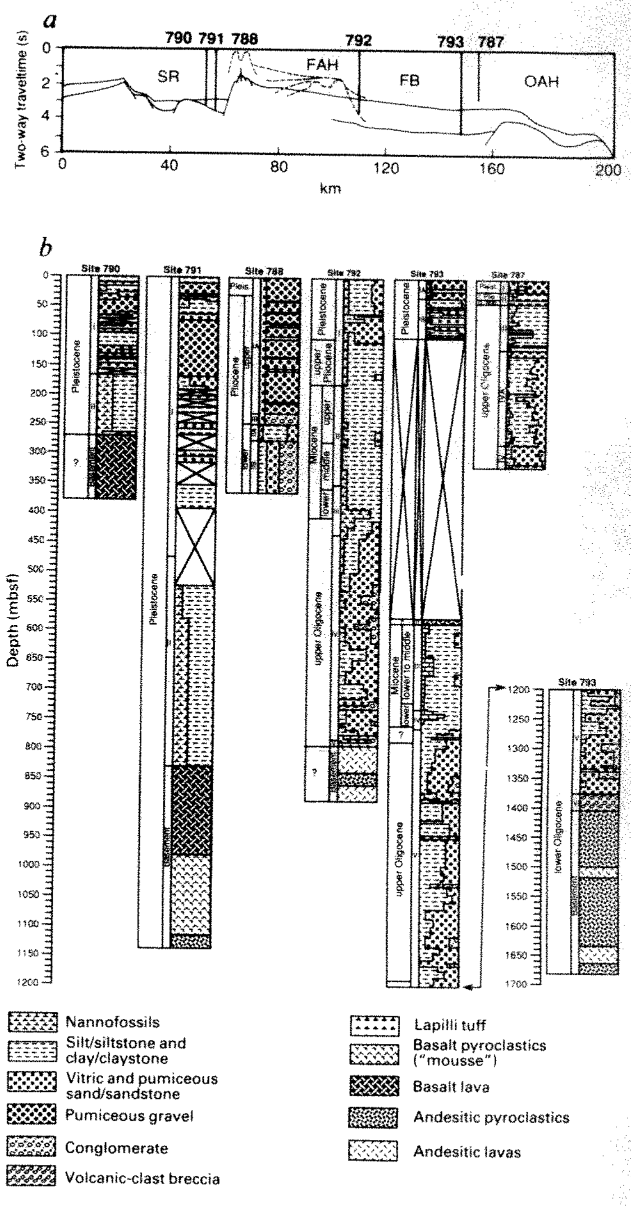


FIG. 2 *a*, Stylized cross-section across the Izu–Bonin arc–forearc showing location of Leg 126 sites. SR=Sumisu Rift; FAH=forearc high; FB=forearc basin; OAH=outer-arc high. *b*, Summary lithostratigraphic columns for Leg 126 sites.

792 are massive flows intercalated with hyaloclastite and breccia layers. They are dominantly porphyritic calcalkaline andesites, but are less enriched in low-field-strength elements such as potassium, rubidium, strontium and barium, than most such arc lavas. A middle Miocene or younger basaltic intrusion, serendipitously cored immediately below the casing at site 793, corroborates pre-cruise multichannel seismic evidence for the presence of sills resulting from Neogene forearc volcanism. Izu–Bonin magmas retained a depleted mantle signature throughout the Tertiary.

The pore-water chemistry was closely monitored to detect hydrothermal circulation, especially in the Sumisu Rift. Although indications of circulating sea water were observed in the forearc basin sites 787 and 792, no evidence of hot water circulation was observed at any site. At sites 792 and 793, however, the most extensively altered pore waters yet recovered by the Drilling Programs were extracted from the volcanogenic sediments below 500 and 800 m below sea floor, respectively. The calcium concentrations are up to 170 and 300 millimolar, respectively. The magnesium concentrations are below detection, sulphate profiles are controlled by the precipitation of gypsum, and at site 793, chloride concentrations exceed 700 millimolar. These highly altered interstitial waters are attributed to the low-temperature alteration of plagioclase and volcanic glass into smectites, zeolites and gypsum, in a virtually closed system, as indicated by the high formation factors. □

GLOBAL SEA LEVELS

Floodwaters mark sudden rise

M.J. Tooley

GIVEN the wide public concern about the scale of rise in sea level that will occur as a result of the current global warming, many will be intrigued by new studies[1] by J. Shaw of flooding events at the end of the last glacial. From the evidence of erosion and deposition in Saskatchewan, Canada, Shaw concludes that a rise of several metres could have occurred in a few years. Indeed, a catastrophic release of turbulent meltwater from Livingstone Lake, amounting to as much as 8.4×10^4 km^3, could have raised the sea level by 23 cm in as little as a few weeks.

In an attempt to predict the effect of global warming on the sea, earth scientists have analysed the sedimentary record left by past changes. It is clear that the amplitudes of changes vary wildly between different geological eras, although none is as dramatic as that inferred by Shaw.

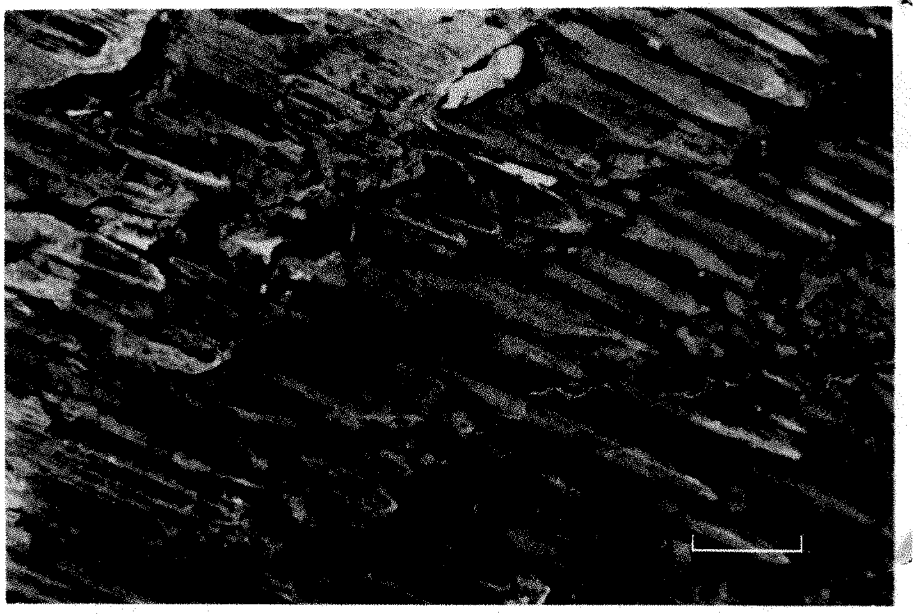
The maximum rate of rise[2] of sea level during the recent geological past (the Holocene or last 10,000 years) did not exceed 22 mm a year. However, this mean value obscures the fact that periods of rapid sea-level change are indicated by analyses of empirical data. In my studies[3,4] in the Ribble estuary, in north-west England, the measured age and altitude of sea-level index points yielded rates of sea-level rise of 34 mm a year about 7,800 years ago; in Morecambe Bay, slightly further north, the rise was 44 mm a year. Corroboration of these rates comes from Limfjord, Denmark, where Petersen[5] showed the rate of sea-level rise to be 46 mm a year between 8,260 and 7,680 years ago. Finally, for Eastern China, Yang *et al.*[6] calculate that the rates for the past 20,000 years have peaked three times at 45, 75 and 20 mm a year, between 15,000 and 11,000 years ago.

Similar rates are forthcoming for the last interglacial age in Europe. At a recent meeting*, H. Streif (Niedersächsisches Landesant Für Bodenforschung, Hannover) concluded that during Eemian II (early in the last interglacial), the sea-level rise was very rapid, possibly 40 mm a year.

These rates of change are several orders of magnitude greater than those calculated for pre-Quaternary periods. For example, during two periods of rapid fall and rise of sea level in the late Cretaceous (over 65 million years ago), rates seem not to have exceeded 9 mm per century[7].

A severe difficulty in these studies is the time resolution for periods of rapid sea-level change, determined with radiometric and luminescent dating techniques. For my Holocene data from coastal Lancashire, the period of rapid sea-level rise is fixed at one site where radiocarbon assays on organic material immediately subjacent to marine silts yielded ages of 7,820±60 and 7,605±85 years. Taking the dates with one standard deviation, there is a 66 per cent chance that the rise of sea level occurred during a period of 360–70 radiocarbon years; with 2 standard deviations, there is a 99 per cent chance that this event occurred within 505 years or instantaneously. Also, the altitudes obtained (−9.6 m and −2.3 m) are present-day measurements and have been affected by sediment consolidation, so that the 7.3 m measured sea-level rise is minimal.

Rapid rates of change are not confined to the oceanic part of the Earth's hydrosphere, and those associated with climate require examination. Bryson *et al.*[8] described the catastrophic disintegration of the Laurentide ice sheet in North America within a couple of centuries about 8,000 years ago, which accounts for the rapid rates of sea-level rise recorded in north-west England and Denmark. The dis-



Aerial photograph of erosional drumlins cut from bedrock in the Northwest Territories, Canada. Shaw uses an analysis of these to infer a massive rate of flooding from the Laurentide icesheet. (Scale bar, 1 km; from ref. 1.)

charge of flood waters, calculated to be 2.0×10^3 km^3, from glacial Lake Missoula is an often-quoted and cyclical event[9]. And Dansgaard *et al.* recently described in *Nature*[10] the abrupt end of the Younger Dryas cold period 10,700 years ago, and concluded that a warming of 7 °C in southern Greenland was completed in 50 years and the climate of the North Atlantic region became milder and less stormy in less than 20 years as the sea-ice cover retreated.

Emiliani *et al.*[11] showed that the discharge of freshwater into the Gulf of Mexico from the Laurentide ice sheet left a clear signature in the ^{18}O isotope record from the sediment cores. Two peak values in the ^{18}O levels about 15,600 and 13,000 years ago now lead Shaw[1] to suggest that they result from two catastrophic meltwater floods from subglacial landform fields. The evidence for such floods comes from an analysis of extensive fields of drumlins — erosional and depositional features — in northern Canada (see figure).

Shaw concludes that rapid changes of sea level may not be a direct consequence of melting arising from climatic causes, but may arise from glacial hydrological causes alone: that is the accumulation and flow of meltwater in reservoirs beneath the ice. Climatic fluctuations then become, in part, a consequence rather than a cause of meltwater floods which could act as a coldwater lid over the North Atlantic ocean, profoundly affecting climatic parameters, such as temperature and evaporation, the stability of the water column and the oxygen isotope signatures in the sedimentary record.

There are implications for the modelling of future sea-level rise, linked, as it is in present investigations, to predicted global temperature rise. The conservative estimates of future sea-level rise given by Hoffman[12] for AD 2025 and AD 2050 are 13.0 and 23.8 cm, respectively — equivalent to a sea-level rise of about 3 mm a year. At a second recent meeting[†] T. Wigley (Univ. East Anglia) concluded that the best estimate of the sea-level rise by AD 2050 was 24–38 cm, or between 3 and 6 mm a year, which is 3–4 times greater than the so-called global rates during the past 100 years calculated from tide gauge data[13]. The impacts of such rates on natural and embanked coasts of the world cannot be underestimated. These rates approach or exceed the critical rate of 5 mm a year calculated from empirical data[14] from the Lincolnshire Fenland when periods of coastline retreat and marine transgression occurred during the past 6,500 years.

None of these rates, however, approaches the rapid rates of sea-level rise recorded from the stratigraphic record of the last interglacial, the culminating stages of the last glaciation and the early part of this interglacial. The present lack of a precise dating technique leads to the conclusion that even the measured rapid rates of sea-level rise between 22 and 75 mm a year may be conservative. The evidence presented by Shaw tends to confirm this conclusion.

Three questions remain, however. First, Boulton[15] concludes that in the absence of evidence for large-scale drumlin formation associated with the catastrophic release of meltwater from beneath glaciers, drumlins are a product of the interaction between a glacier and sediments on its bed. Shaw's explanation of drumlin formation is one of many. Second, Shaw's hypothesis for subglacial, drumlin-forming floods needs to be extended to Fenno–Scandinavia and tested. Third, is there a potential on the Earth now for catastrophic, subglacial floods raising sea level by 23 cm in a few weeks or several metres in a few years? □

Erratum

It should have been acknowledged that the figure accompanying the News and Views article in *Nature* **341**, 22–23; 1989 by James Scott was based on an unpublished figure of K. A. Hajjar and R. L. Nachman. The published figure contains additional information based on refs 1–3 of the article. In the second paragraph of the article it should have been stated that the apo(*a*) molecule has 37 or more repeats of plasminogen 'kringle IV' not V1.

CONSERVATION BIOLOGY

Divided the fruitflies fall

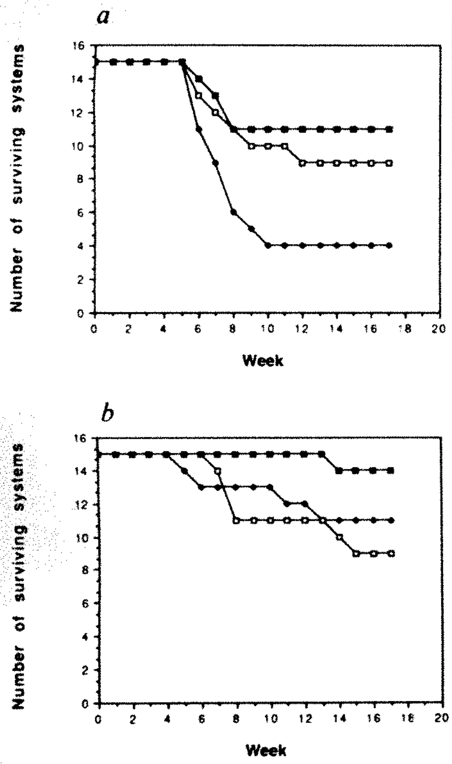
Rolf Anker Ims and Nils C. Stenseth

P 38,673

MAN's destruction of habitat continues to be the leading cause of species extinction[1,2]. It not only reduces the total area of suitable habitats, but also leads to the fragmentation of large continuous populations into smaller, more or less isolated subpopulations. Dynamics within clusters of such subpopulations can be complex[3] because of interactions between numerous factors, such as the degree of subdivision of the subpopulation, the spatial configuration of the habitat fragments and basic population parameters including the rate of increase, dispersal rate, gene flow and social organization. The outcomes of such interactions are very difficult to predict, and such predictions are today almost exclusively derived from simple mathematical models[4]. But Forney and Gilpin[5], in a recent study of two species of fruitfly, *Drosophila hydei* and *D. pseudoobscura*, have reintroduced the use of experimental model systems, whereby populations are manipulated in simple environments in the laboratory. Their observations have serious implications for the general predictions derived from current methods of analysis of population dynamics.

Mathematical models for predicting population dynamics have been criticized for being too simplistic and inconsistent, often disregarding essential population processes[4,6]. This criticism is illustrated by the current debate over whether single large reserves or several small reserves are the most effective[7,8]. Mathematical models present a dilemma: simplistic models have the advantage of being open to thorough analysis but are intrinsically general in nature, whereas complex models that reflect reality more accurately, by way of assumed processes, cannot be analysed thoroughly. The alternative approach, using experimental model systems, strives also to predict population changes from habitat fragmentation by isolating and manipulating the set of factors presumed to be most important. Experimental systems are generally more realistic, and more suited to the study of behavioural responses of organisms to the entirely new conditions created by man. They can, in fact, provide both predictions about real-world phenomena and tests of mathematical models.

In their new study, Forney and Gilpin have compared the fate of *Drosophila* in



The number of surviving replicates in the different experimental systems as a function of time for *a*, *D. pseudoobscura* and *b*, *D. hudei*. ◆, Separated system; □, connected system; ■, large system.

three environments: one in which the original population is divided in two, each subpopulation being confined to a separate culture bottle; a similar system in which the bottles are connected by a corridor that allows migration at the rate of one fly each generation; and a large unified system, in which the initial population and total habitat were twice that of the other systems. Each system, replicated 15 times for both species, was run for 6–8 generations.

Although the total volume of habitat and the total amount of food provided were expected to facilitate subpopulation sizes larger than 20–50 (regarded as the minimum viable size for populations[6]), many of the populations became extinct. Extinctions were, however, less common in the larger system, a twofold increase in population space yielding a sixfold increase in the mean time to extinction. In the separated system large density fluctuations sometimes caused the isolated subpopulations to fall below the minimum viable size, resulting in extinctions due to demographic stochasticity.

Interestingly, the two *Drosophila* species responded differently to the experiment (see figure). *D. hudei* survived better than *D. pseudoobscura* in large and separated systems owing to its higher average population density. *D. pseudoobscura*, on the other hand, survived better in the connected system than in the separated system, and better than *D. hudei* in the connected system, because of a higher dispersal ability, which tended to dampen the population fluctuations within subpopulations.

Forney and Gilpin conclude, somewhat unsurprisingly, that large, continuous populations are more viable than divided ones. Migration corridors, however, do not seem to compensate for this difference[9], a finding of particular relevance to the debate over whether such corridors are effective in maintaining populations in conservation areas. Furthermore, the very different response by two closely related species questions the generality of predictions derived from mathematical models.

The robustness of these results can only be assessed when their experimental design has been replicated for other experimental model systems and under different conditions. Future experiments performed under simplified laboratory environments should be complemented by experiments under more complex and realistic, seminatural field conditions. One such experiment, using an insect predator–prey system, has already been published[10]. Our model experiments and those of M. Gaines and R. Holt (University of Kansas) are of the same kind as those by Forney and Gilpin, but use small mammals in manipulated landscapes.

Relative to studies on natural populations, experimental systems are inexpensive in terms of time, labour and money. This facilitates adequate replication and consequently high statistical significance of the results. Of course, experimental model systems can never replace studies on natural systems, but they may aid in the design of large-scale field projects which thereby could more easily focus on the most significant of the 'jungle' of processes operating in any natural system. Model systems can also provide the spatial and temporal scales[11] required for studies on such natural systems. But, more importantly, experimental model systems may provide an insight of profound value to conservation biologists fighting against the rapidly growing number of species heading for extinction and may indeed be an important complementary approach to the conventional methods of population analysis. □

DAEDALUS

Flash and bang

Conventional explosives are dangerously powerful. They have to be, as each small volume of explosive must release enough shock energy to fire the adjacent volume: that is how an explosion propagates. But Daedalus points out that some explosives escape this limitation. A mixture of hydrogen and chlorine, for example, is photosensitive. An intense flash of light can shine through the whole volume and set it all off without any shock having to traverse it. DREADCO's chemists are now exploiting this principle to create new, safe, feeble explosives.

They are synthesizing nitro-substituted polymer-chain molecules with a photosensitive 'detonator' group at one end of the chain. When exposed to the right wavelength of light, the detonator photodissociates, and a radical decomposition explosion propagates down the chain. The molecular 'gain' (energy released per absorbed photon) can be increased simply by lengthening the chain. A dilute solution of this explosive could never detonate or propagate an explosive shock: its energy density would be too low. But a flash of the right wavelength could fire every photoexplosive molecule in it.

The resulting feeble liquid-phase explosion would heat the solvent to a temperature depending on the initial concentration. Window cleaners, campers and swimming-bath attendants should welcome a harmless powder which dissolves readily in water, and raises it instantly to a chosen temperature when fired by a special flash gun. The sudden expansion would give only a small shock. It should not damage the containing vessel, though the brief molecular agitation might usefully kill suspended bacteria. The disengaged nitrogen and carbon dioxide might also give the water a mild but invigorating fizz.

Dispersed in transparent plastic material, Daedalus's photo-explosive will give a novel photographic film. Exposed in a suitable camera, it will explode only in the bright areas of the image. The sudden local heating and expansion could stamp a metal backing sheet into an instant printing plate. Or it could locally melt the plastic, letting it absorb a backing pigment to create a sort of photographic oil painting.

Daedalus's photo-meltable explosive polymer will also make a wonderful instant glue. The chosen kit of parts need only be clamped together, with strips of plastic photo-explosive in the joints. The DREADCO flash setting gun will beam its light right through the strips in optic fibre fashion. They will melt and expand explosively, impact glueing the joints with molten resin. The whole assembly — table, cupboard or grand piano — will then be firmly bonded in one dramatic flash and bang.

David Jones

The unbegun Big Bang

SIR—While it is most plausible that "the Big Bang is an over-simple view of how the Universe began", as recently stressed by John Maddox[1], it need not be as "philosophically unacceptable" as he contends. My purpose is to dissent from the common but mistaken idea that Big Bang cosmologies imply "that there was an instant at which time literally began and, so, by extension, an instant before which there was no time".

In truth, the so-called 'initial' instant t_0 corresponds to a singularity of the space-time model (as expressed by the Robertson–Walker metric) which has to be taken at face value: because the model is not defined for $t = t_0$, this value does not belong to its physical time domain. In other words, the continuity, or, more to the point, the contiguity of time breaks down. The range of physical time consists only of the open interval $]t_0, \infty[$; the initial time t_0 is not a moment in the life of the Universe, and does not belong to its past — which *a fortiori* cannot extend before t_0. As such, this out-of-reach instant may be said to be infinitely remote, irrespective of its finite numerical value on a conventional timescale. This crucial point has been stressed by Misner[2] who proposes to treat it as "an essential element of cosmological theory" and suggests that we refine our concepts of time accordingly. His plea, however, has been little heard.

This situation is not so new: it is similar to the concepts of limit velocity c, or absolute zero for temperatures T_0, both of which mark true singularities in the relevant theoretical formalisms and can be considered as infinite, that is unreachable, values. Just as we have become accustomed to the apparent paradox of a zero temperature, below which the concept of temperature breaks down, so we should accept the idea of a time origin before which the concept of time makes no sense.

Furthermore, according to the theoretical framework of modern cosmology, namely general relativity, the choice of coordinates used to describe the Universe is arbitrary. Formally, the spatio-temporal parameters through which the Robertson–Walker metric is expressed, may be modified at will. The usual choice of cosmic time, although convenient, is by no means unique. Thus it is possible, through a suitable redefinition of time, to send back the birth of the Universe to (minus) infinity where, or rather *when* it seems to belong. Such a redefinition, already outlined by Misner[2], can be derived through a simple group-theoretical analysis designed to restore the additivity of time, a property lost by the conventional cosmic time[3]. This new, linear time is defined by using the Universe itself as its own clock through its expansion, and leads to a suggestive re-expression of the Robertson–Walker metric. Naturally, on the linear scale, the lifespan of the Universe is infinite, so that never did the Big Bang begin. Thus, one may agree with the title of the article by John Maddox, *Down with the Big Bang*, provided it is understood as 'down in time' (and infinitely so).

Note that no new physics is involved in the introduction and use of linear time rather than cosmic time. Although it might be fruitful for some computational purposes, its main interest is conceptual.

There is certainly a great amount of work to be done for improving or even replacing the standard Big Bang theory as a description of the primitive stages of the Universe. Let us not confuse, however, the form and the meaning of our theories. If the present ones are certainly open to much scientific questioning, their philosophical status does not seem that disquieting — provided that our own understanding raises to match their subtleties. If, as John Maddox foresees, "creationists will have to retreat to the Big Bang", we have not too much to fear, as this retreat will be but an endless one.

Frozen Neanderthals

SIR—Jared Diamond describes in his News and Views article[1], "The recent spectacular discovery of the first reptile to survive natural freezing". He refers to Storey's 1988 report[2] that hatchlings of the Canadian painted turtle in the laboratory can survive the freezing of 52–53 per cent of total body water at −4 °C and to comparable findings for certain frogs — facts of great significance to their survival in nature. Diamond concludes that "Although the discoveries of the first freeze-tolerant vertebrates seem to bring the dream of thawing out [and resuscitating a frozen Neanderthal] tantalizingly closer . . . they actually push it even further into the realm of science fiction. Only by a series of specialized adaptations lacking in most animals do the painted turtle and the four frog species confine freezing to the extracellular space and so avoid lethal damage".

I agree that obtaining viable frozen–thawed Neanderthals is science fiction — not because they lack specialized adaptations, but rather because to survive millennia, they would have to be maintained at temperatures at which biochemical activity ceases, that is, below −120 °C. Unfortunately, the very act of cooling a whole animal to such temperatures will increase the solute concentrations in its tissues 30-fold or more over normal and will convert essentially all its body water to ice. The result, at least for vertebrates, will be instant death.

The first report of a vertebrate surviving partial freezing to −4 or −5 °C was in 1956, and concerned not a reptile or frog with specialized adaptations but a mammal with no adaptations other than the ability to survive cooling in the absence of freezing to 0 °C and slightly below. In that year Smith and Lovelock[3,4] reported that 30 per cent of golden hamsters survived, without apparent injury, the conversion to ice of 40–50 per cent of their body water as the result of 40–60 min in liquid baths at −5 °C. This result is not dissimilar from those for the painted turtle, except that all four of the latter exhibited no evidence of injury after a 12 h exposure in the partly frozen state to air at −4 °C, at which point half the body water was frozen.

Diamond is correct in emphasizing that survival of whole animals (or of most individual cells) after freezing requires that ice be confined to the extracellular space, but this does not demand that the animal possess special adaptations. Rather, it requires: that the first ice forms with little supercooling, and that it first appears in the extracellular space (which is usually the case); that the subsequent cooling rate is low enough to allow sufficient unfrozen cell water to leave the cells osmotically to keep the chemical potential of the residual cell water close to that of the external ice; or that the temperature does not drop to a level at which ice nucleation of the water in supercooled cells can occur[5]. Specialized adaptations do become important in enhancing the ability of cells and organisms to survive greater quantities of extracellular ice (either by the synthesis of cryoprotectants or by plasma-membrane alterations) or by enhancing their ability to supercool.

Transcriptional silencing and lamins

SIR—The SIR4 protein in the yeast *Saccharomyces cerevisiae* is required for transcriptional silencing of the *HM* mating-type loci and for high mitotic stability of silencer-containing plasmids. As a result of comparing the sequences of proteins involved in DNA replication and transcriptional control, we have noticed that the C terminus of SIR4 (ref. 1) contains 12 in-phase heptad repeats (brackets in upper figure) within a long region of predicted α-helix (rectangles in lower figure). If the amino acids in the heptad repeat are designated (a-b-c-e-f-g)$_n$, residues a and d (circles in the figure) are generally hydrophobic aliphatic amino acids — alanine (A), isoleucine (I), leucine (L), methionine (M), valine (V) — and form the basis for coiled-coil interactions. Of the 24 residues in the a and d positions of the SIR4 heptad repeats, 20 are hydrophobic aliphatic amino acids (closed circles in figure) typical of the heptad repeats found in proteins like myosin, tropomyosin and the intermediate filament (IF) proteins. A computer search[2] revealed that the C terminus of SIR4 is most closely related to the central rod of the human nuclear lamins A and C (23% identity and 36% conservation between residues 123 and 211 of lamins A and C) and that this similarity is not limited to the a and d positions of the heptad repeat. Although lamins A and C are related to other IF proteins[3], the greatest similarity between the C terminus of SIR4 and coil 1b of the lamins A and C lies within a 43-amino-acid region found only in the lamins and not in other members of the IF family (hatched region, residues 120–162 of lamins A and C) suggesting that SIR4 is specifically related to the nuclear lamins.

Comparison of SIR4, lamin and IF. Identical amino acids are marked by thick bars, conserved amino acids by thin bars.

We note that this region of heptad repeat is an essential functional domain of SIR4 (ref. 1). Furthermore, it is far longer than the 'leucine zipper' found in several transcription factors[4] and the extent and degree of SIR4–lamin similarity is far greater than that noted by Murre *et al.* for the immunoglobin enhancer (kE2) binding protein[5]. This region of SIR4 may serve as a dimerization domain, but it is intriguing to consider that it may also directly interact with the nuclear lamina. In support of this, the REP1 protein encoded by the 2-μM circle plasmid of *Saccharomyces cerevisiae* exhibits a comparable extent and degree of similarity to the lamins and has been shown biochemically to be associated with the karyoskeleton[6]. To explain this, Wu *et al.* postulated that the region of REP1–lamin similarity, found at the C terminus of the REP1 protein, interacts directly with the lamins. It is interesting that the role of REP1 in the mitotic stability of 2-μM plasmids is strikingly similar to the role of SIR4 in the mitotic stability of transcriptional silencer-containing plasmids[7]. In addition to its effect on mitotic stability, however, SIR4 is required for transcriptional silencing by cooperating with silencer-binding proteins[8]. In light of the similarity between SIR4 and the nuclear lamins, it is not unreasonable to suggest that silencing may involve association of the HM loci with the nuclear lamina through SIR4.

Database pollution

SIR—We have noted that a number of entries in the Genbank, EMBL and NBRF nucleic-acid databases contain vector sequences. We compared three vector sequences (plasmid pBR322, phage M13 and λ-phage) with the sequences in the three databases (GenBank release 59.0, EMBL release 18.0, and NBRF-Nucleic release 34.0) and found that overall there are 62 entries that contain unnecessary vector sequence. Most of these entries (52) contain vector sequences which have no serious consequences (that is, vector sequence was left on the end of a submitted sequence). But 10 of the 62 entries contain vector sequences where the authors have made serious mistakes in interpreting their sequence data. These include, a recent entry on GenBank (accession number M19035) that contains a portion of M13, including part of the polycloning site, in the middle of the presumed protein-coding region. Another two (numbers X05793 and X13410) contain vector sequence within supposed coding regions discussed in the papers and six entries (numbers M10384, M14896, M18076, M21517, V00745 and X12660) that are described as unique sequence are almost entirely vector sequence. These problems would certainly have been avoided if the authors had compared their sequence data with available vector sequences.

In addition to these unwarranted inclusions, there are 9 entries on three databases that contain vector sequences which may be warranted but do not have sufficient documentation.

Inclusion of vector sequence in unique sequence entries adds an unnecessary complication to searching the databases. In some cases it is necessary to include vector sequence in a database entry (such as in fusion constructs), but inclusions of this nature should be clearly annotated. It is not the responsibility of database managers or reviewers to weed out unnecessary sequence information. The responsibility rests firmly with the authors of the sequence.

We have informed GenBank of the sequences in question.

Essential Research Journals from Churchill Livingstone . . . .

MEDICAL JOURNALS

Churchill Livingstone have a well known and established list of medical journals including the **prestigious research journals** listed below.

Cell Calcium **Editors: R M Case and A Scarpa**, publishes work from all branches of science and medicine on the regulation of cell calcium or the regulation by calcium of cell function. Papers are refereed and published rapidly, providing the latest discoveries in the field.

Neuropeptides **Editors: M J Brownstein and J Hughes**, presents original research and review articles on all aspects of the biology and chemistry of peptides derived from, or acting on, the nervous system. Providing the essential resource for researchers in neuroscience, neurology, endocrinology and pharmacology.

Prostaglandins, Leukotrienes and Essential Fatty Acids. Editor: D F Horrobin The scope and depth of the journal is now greater than ever before with high quality papers, including some review articles, on all aspects of prostaglandins, leukotrienes and essential fatty acids. Now publishing 12 issues a year.

New for 1990. . .

Lithium. Editor: F N Johnson. This new journal will publish selected high quality articles on all biomedical aspects of lithium, i.e. biochemical, physiological, pharmacological, psychopharmacological and clinical. The aim of Lithium is to provide a single outlet for these varied research themes, and so to unify the subject of lithium research and therapy. Published articles will represent important new directions in the study of biological effects of lithium.

If you would like any further information on these or any of our journals please contact: Suzanne Casey, Sales Promotion Executive, Churchill Livingstone Medical Journals, Robert Stevenson House, 1-3 Baxters Place, Edinburgh, EH1 3AF, UK

GIFT BOOKS

H.-O. Peitgen, D. Saupe, University of Bremen (Eds.)

The Science of Fractal Images

2nd printing 1988. XIV, 312 pp. 142 illus. in 277 parts, incl. 39 color plates. Hardcover DM 69,- ISBN 3-540-96608-0

The Science of Fractal Images is a new book discussing fractals from a computer graphic viewpoint. It is based on a SIGGRAPH '87 course given by these five recognized leaders in the field:

- **Michael F. Barnsley:** Fractal Modelling of Real World Images
- **Robert L. Devaney:** Fractal Patterns Arising in Chaotic Dynamics
- **Heinz-Otto Peitgen:** Fantastic Deterministic Fractals
- **Dietmar Saupe:** Algorithms for Random Fractals
- **Richard D. Voss:** Fractals in Nature: Characterization, Measurement and Simulation

H.-O. Peitgen, P. H. Richter, University of Bremen

The Beauty of Fractals

Images of Complex Dynamical Systems

1986. XII, 199 pp. 184 figs., many in color. Hardcover DM 84,- ISBN 3-540-15851-0

Intellectually stimulating and full of beautiful colour plates, this book is an unusual attempt to present the field of Complex Dynamics. The astounding pictures assembled here invite the general public to share in a new mathematical experience: to revel in the charm of fractal frontiers.

H. W. Franke, Puppling

Computer Graphics – Computer Art

2nd rev. and enlarged ed. 1985. XII, 177 pp. 133 figs., some in color. Hardcover DM 149,- ISBN 3-540-15149-4

Technology and aesthetics, computers and art in fascinating interplay.

O. Medenbach, Bochum; **H. Wilk,** Taunusstein

The Magic of Minerals

1986. 205 pp. 110 color photographs. Hardcover DM 128,- ISBN 3-540-15730-1

This atlas describes over 100 selected minerals, each illustrated by stunningly beautiful, full-page colour photomacrographs.

Springer

R. Heister, St. Augustin

Dictionary of Abbreviations in Medical Sciences

With a list of the most important medical and scientific journals and their traditional abbreviations

1989. VIII, 287 pp. Hardcover DM 58,- ISBN 3-540-50487-7

Tripped up by medical and scientific abbreviations? By ABC, ABF, BALT, BEIR, DCN...Here's the ideal quick reference!

D. Kipnis, Philadelphia (Ed.)

Technology and Power

1990. Approx. 190 pp. Softcover DM 58,- ISBN 3-540-97082-7

This book focuses on the psychology of those who control technology and therefore wield power. It shows how the successful exercise of power changes powerholders' relations with those they influence; indeed, the added power provided by technology alters for the worse social relations between managers and employees, physicians and patients, colonialists and the colonized, and social-science practitioners and their clients.

A. Warhol, New York; **K. Benirschke,** San Diego

Vanishing Animals

1986. IX, 99 pp. 16 original, full-color plates. Hardcover DM 120,- ISBN 3-540-96410-X

Art and science come together in this striking portrayal of some of the most endangered animals in the world. Andy Warhol has created large-format full-color plates (silkscreen over collage) especially for this book. A stimulating text by Dr. Kurt Benirschke, leading pathologist and former Director of Research of the San Diego Zoo, lets you discover the lives and habits of these animals – and what the outlook is for their survival.

K. V. Laurikainen, University of Helsinki

Beyond the Atom

The Philosophical Thought of Wolfgang Pauli

1988. XIX, 234 pp. 10 figs. Softcover DM 68,- ISBN 3-540-19456-8

Contents: Introduction. – Positivism and Realism. – The Reality of Opposites. – The Metaphysical Roots of Science. – Spirit and Matter. – The Limits of Knowledge. – Mysticism. – The Problem of Evil. – Quaternity. – Transcendental Reality. – Appendices.

J. Altmann, University of Bochum; **J. Rotblat,** London (Eds.)

Verification of Arms Reductions – Nuclear, Conventional and Chemical

1989. Approx. 240 pp. Hardcover Approx. DM 64,- ISBN 3-540-51596-8

How can compliance with international treaties be verified? This book looks at recent developments that affect arms control and disarmament verification, one of the key conditions for maintaining world peace.

A. S. Issar, Ben Gurion University of Negev

Water Shall Flow from the Rock

Hydrogeology and Climate in the Lands of the Bible

1989. Approx. 220 pp. 49 figs. Softcover DM 48,- ISBN 3-540-51621-2

The author focusses on a new model of climatic changes in the last 6000 years and their influence on the peoples of the Middle East. He combines results from the natural sciences with historical documents and archeological findings. Thus various biblical events can be explained by using geohydrological and paleoclimatic developments. An exciting book for geoscientists interested in the recent past and for those interested in the flourishing and decline of civilizations in the Middle East.

Cell Biology from VCH

Plant Cell Line Selection

edited by P.J. Dix

1989. Ca 300 pages, 55 figures and 25 tables.
Hardcover. Ca £ 60.00. ISBN 3-527-27963-6

This book provides detailed treatment of the identification and isolation of modified plant cells. No other text covers this area of plant cell culture technology in comparable depth. Emphasis is placed on the methodology, the selection of variants of agricultural and industrial interest, and cell selection in relation to genetic manipulation. The book is of interest to a wide range of plant cell and molecular biologists, including biotechnologists.

Gangliosides and Cancer

edited by H.F. Oettgen

1989. XVI, 368 pages with 104 figures and 50 tables
Hardcover. £ 63.00. ISBN 3-527-27835-4

The Molecular Biology of Receptors

Now complete:

Biotechnology – A Comprehensive Treatise

edited by H.-J. Rehm and G. Reed

The series of 10 volumes is now complete.
Subscription price per volume: £ 170.00.
Single volume price: £ 198.00.
Total price for the whole series: £ 1700.00.

From a review:
Biotechnology enables one to learn basic microbiology, biochemistry, and engineering. It also emphasizes the discipline's commercial potential by including separate chapters on patents and sources of microorganisms (very important information to those not in the field).
The editors, both of impressive scientific stature, bring strong industrial and academic backgrounds to the work. Reed, the industrialist, has had a most impressive career specializing in yeasts. Rehm, on the other hand, has spent much of his career in an academic setting and is an authority on hydrocarbon assimilation. *Bio/Technology*

Volume 1: Microbial Fundamentals
Volume 2: Fundamentals of Biochemical Engineering
Volume 3: Biomass, Microorganisms for Special Applications, Microbial Products I, Energy from Renewable Resources
Volume 4: Microbial Products II
Volume 5: Food and Feed Production with Microorganisms
Volume 6a: Biotransformations
Volume 6b: Special Microbial Processes
Volume 7a: Enzyme Technology
Volume 7b: Gene Technology
Volume 8: Microbial Degradations
Cumulative Indexes

PROGRESS IN IMMUNOLOGY VII

Proceedings of the 7th International Congress of Immunology, Berlin, 1989
1989. Approx. 1450 pp. 249 figs. 177 tabs. Hardcover DM 236,–
ISBN 3-540-51053-2

West
BERLIN
July 30 – August 5, 1989
7th International Congress of Immunology

Immunology exhibited at its best

Editors: **F. Melchers, E. D. Albert, H. von Boehmer, M. P. Dierich, L. Du Pasquier, K. Eichmann, D. Gemsa, O. Götze, J. R. Kalden, S. Kaufmann, H. Kirchner, K. Resch, G. Riethmüller, A. Schimpl, C. Sorg, M. Steinmetz, H. Wagner, H. G. Zachau**

Editorial Assistance: **L. Nicklin**

Never before has so much progress been reported in immunology as at this congress. The full impact of new technologies developed since the late 1970s has come to fruition: gene isolation, mutation, transfection and expression, protein structure and peptide synthesis, cell cloning, hybridization and monoclonal antibodies, CD serology, SCID and transgenic mice, modern immunomodulation and vaccines. An overwhelming mass of data has accumulated over the last years. The reports are excellent and up-to-date, to a degree no journal will ever achieve, and the results are presented in a concise and lucid way. This report will serve as a guideline for generations of immunologists to come. Hundreds of new avenues have been opened, and an abundance of research tools and goals are indicated. This volume is a treasure trove of explorations ahead of our time – it is exciting reading.
This progress report presents outstanding contributions worth many prizes – a feature which is unusual for proceedings volumes. Immunology is exhibited at its best: an exciting research area and a rewarding subject to study for the benefit of mankind – **today more than ever!**

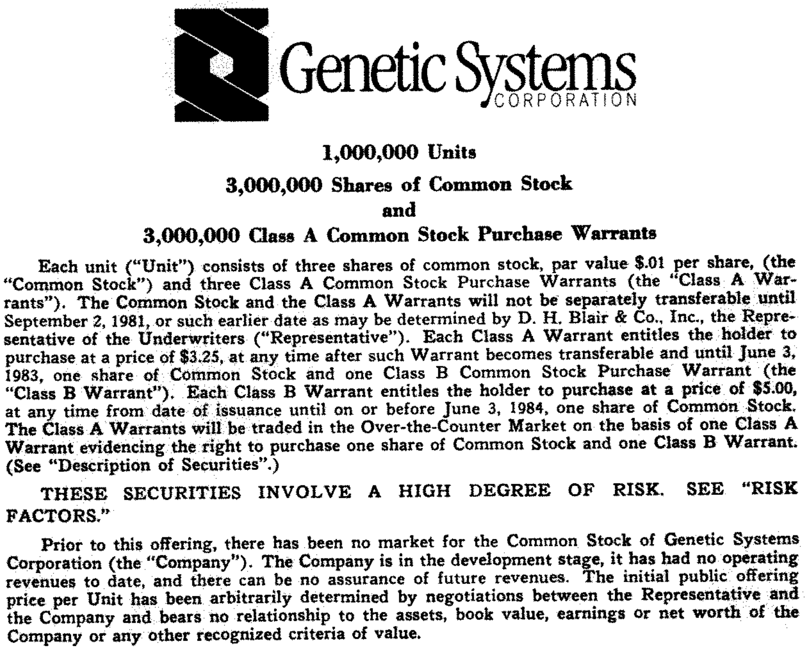
Bulls, bears and bugs

Julian Davies

Gene Dreams: Wall Street, Academia, and the Rise of Biotechnology. By Robert Teitelman. *Basic Books: 1989. Pp.237. $19.95.*

THE rise of modern biotechnology in the 1970s was, with only a few notable exceptions, an American phenomenon. The United States provided a favourable juxtaposition of abundant venture capital and a willingness to take risks, fuelled by the liberal attitude of American universities and their professors. The entire development also rested on the bright young postdocs in molecular biology, who were suddenly provided with a new employment option. Because academic positions were scarce, and conventional industry unattractive, the chance to join like-minded peers in an academic research-style environment under favourable conditions of employment, and without the pressure of grant requests and teaching commitments, was an attractive proposition. The companies themselves were characterized by flexible decision-making, short lines of communication and, above all else, science-based management.



Genetic Systems CORPORATION

1,000,000 Units

3,000,000 Shares of Common Stock

and

3,000,000 Class A Common Stock Purchase Warrants

Each unit ("Unit") consists of three shares of common stock, par value $.01 per share, (the "Common Stock") and three Class A Common Stock Purchase Warrants (the "Class A Warrants"). The Common Stock and the Class A Warrants will not be separately transferable until September 2, 1981, or such earlier date as may be determined by D. H. Blair & Co., Inc., the Representative of the Underwriters ("Representative"). Each Class A Warrant entitles the holder to purchase at a price of $3.25, at any time after such Warrant becomes transferable and until June 3, 1983, one share of Common Stock and one Class B Common Stock Purchase Warrant (the "Class B Warrant"). Each Class B Warrant entitles the holder to purchase at a price of $5.00, at any time from date of issuance until on or before June 3, 1984, one share of Common Stock. The Class A Warrants will be traded in the Over-the-Counter Market on the basis of one Class A Warrant evidencing the right to purchase one share of Common Stock and one Class B Warrant. (See "Description of Securities".)

THESE SECURITIES INVOLVE A HIGH DEGREE OF RISK. SEE "RISK FACTORS."

Prior to this offering, there has been no market for the Common Stock of Genetic Systems Corporation (the "Company"). The Company is in the development stage, it has had no operating revenues to date, and there can be no assurance of future revenues. The initial public offering price per Unit has been arbitrarily determined by negotiations between the Representative and the Company and bears no relationship to the assets, book value, earnings or net worth of the Company or any other recognized criteria of value.

Risk business — the front page of the prospectus released on 4 June 1981 by D.H. Blair & Co., for the flotation of Genetic Systems.

An important difference between the United States and Europe was that in Europe many people sought security and permanence, while in the United States scientists (and investors) were willing to take a chance. The result was that many of them became multimillionaires. For example, the Blech brothers who featured so strongly in the development of the company Genetic Systems (the leitmotiv of Robert Teitelman's *Gene Dreams*) are in the top ten of the list of biotechnology's rich.

In the book, Teitelman describes well the machinations involved in the setting-up, funding and then, in part, the dismantling of a biotechnology company by illustrating the birth, growth (and death?) of Genetic Systems. The company was born with the same scientific idealism as most of the other biotech companies and, like them, with the same naive approach to business and marketing in the real world of commerce. Robert Nowinski, who was one of the founders, provided most of the scientific driving force both in and out of the company. Much of the Genetic Systems story is built around his ambition and omnipotence, and he is essentially the hero (or scapegoat) of the book.

What I remember best about my years with a biotechnology start-up company (Biogen) was the enthusiasm about the science and the quality of the scientists involved. We hired excellent young PhDs who were willing to change their careers to enter a risky business. There was enormous *esprit de corps*, a biotechnology culture if you will, based partly on the entrepreneurial nature of the business, but also on the fact that we knew that we were involved in tight races with equally talented groups — at Genentech, Cetus and similar companies — to get to a scientific goal and marketable product first. We all knew what the 'products' were. The sense of a race was all the more intense because we were well acquainted with the competition as friends, old academic colleagues or classmates, people with whom we had always had a genial relationship.

Another outstanding feature of the start-up days was the business of financing — the wheeling and dealing to raise private or public funds, the tricks and the enormously hard, and in a sense unsatisfying, task of begging at a high level. We were selling ideas and technology only; it was not until 1983 and 1984 that it became apparent that market-driven and not technology-driven philosophies would be necessary to convince the analysts and investors that we were interested in making a profit. I recall the endless discussions with the big boys (the Abbotts and Hoechsts and Roches) and their apparent conservatism which always heightened our view of ourselves as more innovative, original and better than they were. Even now, scanning the positions vacant columns in *Nature* or *Science*, the ego of young biotechnology companies is obvious. They often begin their advertisements by describing themselves as "leaders", "world-wide leaders", "recognized leaders" or even "recognized world-wide leaders", and they are always "innovative". Modesty is not their strong point. The biotechnology start-ups created an entirely new breed of company, of person and of scientific ideal.

A book which captured all aspects of the exciting and frustrating period, 1975 to 1985, would be an interesting piece of work indeed. *Gene Dreams* is not that book; it is both good and bad. Teitelman is at his best when describing the complex and chicane ways of raising and making money by venture capitalists, and also in his accounts of the internecine relationships and conflicts between scientific founders and would-be commercial managers of new biotechnology companies. The various phases of the foundation and development of Genetic Systems, and how a company born of such high scientific expectations should have become the source of so much manipulation in the hands of its scientific and business management, are described vividly. Indeed, much of what Teitelman recounts of Genetic Systems provides substance to some well-aired criticisms of many of the biotechnology start-ups. The constant changes of strategies and of organization, for example, are painful memories of mine.

An overriding impression that emerges from *Gene Dreams* is of the simultaneous power and incompetence of biotechnology investment analysts. As Teitelman points out, these highly paid Wall Street soothsayers were no better than fortune tellers. It is at the same time amazing and depressing that a brief utterance from a Wall Street analyst could drive a stock price up or down in a matter of hours and make or lose fortunes. How can such lack of knowledge yield such power? Who are the gullible, the investment advisors or the investors themselves? Teitelman presents the capriciousness of this business in an excellent manner.

By contrast, much of the scientific commentary in *Gene Dreams* is plain vacuous. Reading parts of the book to colleagues provoked guffaws of laughter. Was it really necessary to depend so much on metaphor and hyperbole? Do oncogenes have "complex splendor"? What is the relationship between a small molecule conjugated to an antibody and a marriage bed? (This sounds like a joke question.) Are some cancer cells like soldiers ducking into a fox hole? Did Genetic Systems really hope to build its business on the "fruits" of early 1980s-style promiscuity? And are viruses the Rosencrantz and Guildenstern of cancer research? In what sense is interferon an endlessly fascinating name like a mythical African Kingdom, or more like Velcro than penicillin (because it is a polymer?). I could continue.

In the book, it is repeatedly stressed that biotechnology has not provided the world with a new industrial revolution (apart from its impact on Wall Street). But an important point is missed with respect to the revolution in basic biology produced by genetic engineering. As a result of this technology, we now have a series of biologically important proteins in pure form and in unlimited quantity. Many of these proteins were not even known 10–15 years ago, and they have now become part of many significant studies of the human endocrine, immune and neural systems. The list of cytokines, ligands and receptors grows weekly; synthetic genes encoding these compounds are available commercially (one company currently offers 30 or more). The interleukins reported to date number up to seven and we should be in double figures soon. There *has* been a revolution in fundamental biology as a result of biotechnology — witness, too, our present understanding of the determinants of taste, smell and sight.

THE DICTIONARY OF CELL BIOLOGY

edited by
J.M. Lackie and J.A.T. Dow

December 1989, c.320 pages,
Paper: ISBN:0.12.432561.0, £9.95
Case: ISBN: 0.12.432560.2, £19.00

The Dictionary of Cell Biology presents nearly 4000 terms which cover classical cell biology and spill over into the adjacent fields of molecular biology, genetics, neurobiology, physiology, immunology and pathology. Synonyms are provided where necessary and cross-references link terms that are related.
Essential for students and researchers in cell biology and related areas.

Available From Booksellers or From :
Academic Press, 24-28 Oval Road, London, NW1 7DX, England

Academic Press, 1250 Sixth Avenue, San Diego, CA 92101-4211, U.S.A.

Reader Service No.6

> "The concept we started with is now a reality. Our products represent a fundamental shift in medicine, and they're not just working — they're hallmarks."

Reality or hyperbole — Robert Nowinski, founder and provider of much of the scientific driving force behind Genetic Systems, speaks to the shareholders in the 1984 annual report.

Teitelman also insists that the biotech companies have failed when, like Genetic Systems, they sign over their rights (and often more) to large multinationals. Why the crocodile tears? Each of the two parties now has what it did not have before; the one gains financial security, business, organization and marketing services, the other flair, innovation and modern technology. And although he is right in saying that, in business terms, the biotechnology industry has not come up to expectations, that begs the question of who raised the expectations in the first place. The answer, I fear, is mostly the public relations people.

Gene Dreams is undoubtedly a good read. It is relatively free of errors (although I take exception to the suggestion that the word 'biotechnology' was invented on Wall Street) and gives a realistic presentation of what has happened, and is happening, in the venture-capital field with respect to the attempted development of an industry based on biotechnology. Teitelman also provides an accurate picture of the internal and external conflicts affecting biotech companies, and the larger-than-life personalities involved. But this book does not do for its subject what Horace Judson's *Eighth Day of Creation* did for the molecular biology of the 1950s–1970s. For that, someone such as Judson with a more subtle journalistic style, and the ability to capture the scientific excitement as well as the business intrigues, will be needed. There is a cracking story to be told, so why over-embellish and sensationalize it? ☐

DNA in flux

J.R.S. Fincham

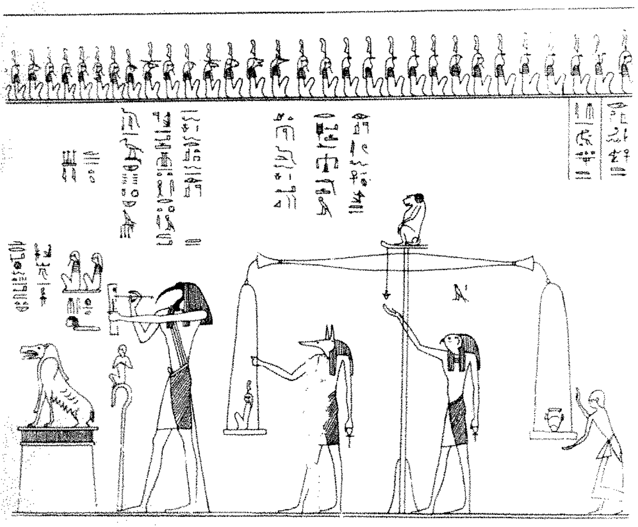
Mobile DNA. Edited by Douglas E. Berg and Martha M. Howe. *American Society for Microbiology, 1913 I Street, NW, Washington, DC 20006: 1989. Pp.972. $75 (ASM member), $95 (non-member).*

AT THE level of the DNA sequence, chromosome structure is in a state of constant flux, usually slow but sometimes surprisingly rapid. Many processes subversive of conventional genetics have evidently been going on for aeons in the natural world, and over the past several decades descriptions of them have greatly proliferated in the scientific literature. The last attempt to pull the whole complex of phenomena together in a single volume was in 1983, when J. Shapiro edited the monograph *Mobile Genetic Elements* for Academic Press. Now Berg and Howe, supported by the American Society for Microbiologists, have provided us with a more than adequate update.

The 43 chapters by different authors cover several very different kinds of genomic change. First there are the well-controlled DNA rearrangements through which organisms of various kinds can create adaptive diversity from a common initial cell type. These include, in vertebrates, the differentiation of cells of the immune system (only immunoglobulin heavy-chain-class switching is dealt with here) and many examples of DNA-based clonal diversification in bacteria and protozoa.

The second kind of DNA mobility is due to the activities of parasites, and includes the integration and excision of the genomes of temperate bacteriophages such as phage-λ and Mu-1, the insertion of reverse transcripts of retrovirus genomes into the chromosomes of animals and plants, and the so far isolated case of insertion of a plasmid DNA segment into plant chromosomes as part of the infection strategy of *Agrobacterium tumefaciens*. From the point of view of the parasite, if not of the host, these processes are precisely controlled and clearly adaptive.

We enter a much more problematical area when we come to the great range of repetitious DNA sequences, present to a greater or lesser extent in virtually all organisms, that have been described, always in derogatory terms, as 'selfish', 'ignorant' or 'junk'. What they all have in common is the capacity to appear at new sites in the genome, though the frequency with which they move varies enormously. Some of them look like dead or crippled retrovirus genomes or, like the retrovirus-related elements best studied in yeast and *Drosophila*, seem to have settled to the role of benign molecular parasites, no



Matters of the heart — Ancient Egyptians believed the heart to be the seat of thought, emotion and intelligence — essential to both the living and dead. This reproduction of a twelfth-century BC papyrus shows a heart from the dead being weighed against a feather which represented law, truth and order. Entry to the afterlife was allowed only if the feather outweighed the heart. Taken from *The Medical Skills of Ancient Egypt* by J. Worth Estes, published by Watson.

longer forming infective particles and only occasionally moving to new chromosomal sites through transcription into RNA and reverse-transcription back to DNA. Others, like the IS elements and transposons of bacteria, the P element of *Drosophila* and the numerous transposable elements now identified in maize and antirrhinum, seem to move quite actively by excision and reinsertion without an RNA intermediate. They resemble the retrovirus-related elements only in encoding the enzymic apparatus for their own movement. Whether the so-called LINES (long interspersed sequences), so abundant in mice and men, are self-moving remains a moot point — they have long open-reading-frames that could code for something with a rather remote resemblance to a reverse transcriptase.

Beyond these there is a host of apparently 'ignorant' sequences which are strongly suspected of having been amplified and dispersed willy-nilly by virtue of reverse transcriptase activity provided by something outside themselves. These elements include pseudogenes (excluded from this volume, presumably because they have no ability to move again) and a great host of SINES (short interspersed sequences) that evidently derive from abundant small RNA molecules transcribed by RNA polymerase 3. SINES are thought to be capable, at least until they decay by mutation, of multiple rounds of proliferation because they carry their own transcriptional promoters with them when they move.

Berg and Howe's compilation extends somewhat beyond these topics to include chapters on illegitimate recombination of DNA in prokaryotes and eukaryotes. M. Meuth's article on eukaryotes is particularly interesting but, surprisingly, does not address the question of how cells of higher eukaryotes are apparently able to integrate into their chromosomes any random bit of non-homologous DNA that is fed to them. Perhaps there is nothing yet to be said on this strange property, on which nearly all current transgenesis experiments depend.

Given that the net was cast so wide, it is perhaps a pity that certain other topics peripheral to the main theme were not included. For example, the tandemly repetitious species-specific 'satellite' DNA arrays found particularly in heterochromatin must certainly have resulted from amplification and dispersal relatively recently on an evolutionary time scale. The mechanisms through which this may have happened are at least worth thinking about. There could be a connection with the spectacular specific gene or chromosome-segment amplification that mammalian cells are capable of under special conditions of selection or stress. Such amplification arguably deserved more than the brief mention and diagram that it gets in Meuth's article.

All of the chapters are by authors with deep experience of their respective subjects. Some, for example Varmus and Brown's 56-page article on retroviruses, with its 397 references, might have been marketable as admirably concise mini-monographs in their own right. The general layout of the book is attractive and clear, much in the style of *Microbiological Reviews*, with a detailed contents page preceding each chapter and plenty of headings and subheadings to help one find particular bits of information.

My only serious reservation about this authoritative and useful volume is that no attempt has been made, either implicitly in the arrangements of the chapters, or explicitly in the form of a general introduction or summary, to provide a scheme of classification of the very diverse phenomena described. Taxonomy may or may not represent real phylogenetic or mechanistic relationships, but at least it helps one to get a mental grip on what may otherwise seem a maze of phenomena. ☐

Between Tethys and Pacific

A.M.C. Şengör

Geological Evolution of South-East Asia. By Charles S. Hutchison. *Clarendon: 1989. Pp. 368. £65, $135.*

Geological Evolution of South-East Asia forms a connecting link between the two previous volumes in the *Oxford Monographs on Geology and Geophysics* (*The Geology of China*, published in 1986, and *Phanerozoic Earth History of Australia*, 1984). It is a most welcome addition to the series, for it deals with an area about which no modern comprehensive regional treatise exists.

Hutchison's text consists of nine principal chapters arrayed in an unusual order. Following a seven-page introduction, which is devoted mainly to a review of the history of geological studies in the individual countries covered in the book, Hutchison goes on to describe the familiar late Mesozoic and Cenozoic tectonic features such as island arcs, back-arc basins, small oceans, microcontinents, and the main fracture systems of South-East Asia. Chapter 3 is reserved for a description of the Cenozoic sedimentary basins, and here I applaud the author's view that "it is preferable to use terminologies related to the elements of plate tectonics". He erects 12 categories of basin, representing divergent, convergent and intra-plate environments. A curious omission here is strike–slip related basins and some of the more prominent of such basins in South-East Asia are hidden under Hutchison's only unfortunate category, that derived from an influential but misleading basin classification, the uninformative "Pannonian-type".

Chapter 4, "Phanerozoic Tectonic Framework", is an introduction to and a synopsis of the following five chapters. Hutchison defines the sutures and the suture-bound blocks in the region and gives a review of the tectonic evolution, much of which seems to be based on Y.G. Gatinskiy's doctoral thesis published in Russian in 1986 and to have inherited its schematism. Although Hutchison pays lip service to terranology ("the region represents an assemblage of terrains"), he wisely avoids the much-ventilated 'terrane analysis' and sticks to describing the suture-bound blocks of both Cathaysia and Gondwana-Land affinities, plus the intervening sutures together with their ophiolites. Finally, Chapters 8 and 9 cover "The Great Sunda-Pacific Volcanic Arcs", and Hutchison's long-term love, "Granite and Associated Plutonic Rocks".

I have mostly good things to say about this book. In the preface, the author candidly states that

> This is not a standard regional geology, and the selection of the title allowed me to emphasize tectonic models, but at the same time to document the stratigraphy and igneous events. I have always taught my students that every aspect of geology involves interpretation . . . . This book is, therefore, a personal interpretation of the region.

In addition, it contains much information on Tertiary oil and gas basins, but "Unfortunately, mineral deposits [Hutchison's speciality] have been excluded due to length constraints". Hutchison is meticulous in his documentation and conscientious in his presentation. I disagree with a number of his interpretations, but am happy to see that he almost always mentions the alternatives and gives references to them.

The 30-page reference list at the end of the book is an invaluable introduction to the scattered sources of information in South-East Asia, and some of the few critical omissions (for example, the 1986 thesis of N. Sikumbang on late Cretaceous obduction in the Meratus Mountains) are readily excusable given the author's remoteness from large geological libraries. The volume is well produced, and is richly illustrated by line drawings of maps, stratigraphic columns and sections; 17 photographic plates are also included. A drawback here, though, is the paucity of seismic reflection profiles.

All those interested in the geology of South-East Asia, especially its terrestrial parts, or in Tethyan tectonics in general, will benefit from reading Hutchison's book. Because of the tremendous tectonic diversity it documents, it will also be a handy reader for a general course on tectonics at the post-graduate level. ☐

A.M.C. Şengör, currently a Royal Society Visiting Research Fellow at the Department of Earth Sciences, University of Oxford, is in the Geology Department, Faculty of Mines, Istanbul Technical University, Ayazaga, Istanbul, Turkey.

Growing pains

John de la Mothe

E. W. R. Steacie and Science in Canada.
By M. Christine King. *University of Toronto Press: 1989. Pp.243. $40, £24.*

In 1939 when the photochemist, E. W. R. Steacie, left McGill University to become Director of the National Research Council's (NRC) Chemistry Division, science in Canada was just beginning to become a force to be reckoned with. Until the late 1930s, Canadian science had been in an embryonic state and was far from being world-class. Christine King's intention is to tell how, in the next 20 years, a transformation came about in large part because of Steacie's efforts.

The shallowness of science's roots in Canada can be gauged from the situation in 1918. Then, only 11 doctoral degrees in science had been granted in the entire country; only two or three universities had what could be considered extensive research programmes; and the total value of industrial research and development performed in the country was estimated at less than $135,000 per year. The NRC — which had been founded in 1916 and which had been given the broad mandate of stimulating and coordinating research and development in Canada — had yet to make much of a mark. But what had begun as a one-person operation with an annual budget of $91,600 had grown, by the time of the outbreak of the Second World War, to an institution with a staff of 300, a budget of nearly $1 million and a substantial building of its own. The NRC was to gain further strength during the war and afterwards burgeon into a centre of excellence to which researchers from five continents would gravitate.

The first years of peace were good for Canada. The economy was booming, money was plentiful and the ministers of the Liberal government were sympathetic — even enthusiastic — about building the NRC. The research assistance which the NRC had begun to give to Canadian industry during the war continued with increasingly recognizable (and recognized) effect. Agricultural machinery, mining and transport equipment, construction standards, and pulp and paper processing were all areas which became acknowledged Canadian strengths worldwide.

During this period, industrial research was only one facet of the NRC's activities. With the energetic involvement of Steacie as Director, and later as Vice-President and then (in 1952) as President, the NRC actively promoted the development of a university research system in Canada. Among the obstacles were the antagonism of the big universities to the NRC, as well as the growing sentiment among politicians that the NRC's large budgets should first be questioned, and then, if approved, fed directly into Canada's economic development (and not its ivory towers). In the early 1950s, Steacie negotiated in masterly fashion with the universities and with government officials on three basic propositions: that the universities' duty is to "give society what it needs, rather than what it wants"; that the university is the cornerstone of any nation's research system and capability; and that Canada would suffer a severe shortage of scientific researchers, and run the risk of losing ground economically to other nations, unless something was done.

Steacie's arguments were hard fought but ultimately well received. Of particular importance was his idea of the NRC's postdoctoral fellowships, which would bring scientists to Canada on "princely stipends". As a result of this programme and the NRC's growing research reputation, many researchers not only came to Canada, but stayed, thereby helping to build the university system.

All was not plain sailing, however, either for the NRC or for Steacie. In 1958, the incoming Conservative government immediately began moves to bring the NRC into the civil service. As in Britain, the scientific civil service was a poor relation in terms of both salary and stature. It was a change of policy that was bitterly resisted as it spelt greater management and political accountability for NRC's researchers, and the end of their freedom of scientific enquiry.

In the end, the political pressures won out. But in 1962, when Steacie died of cancer, he had undoubtedly become the greatest figure in Canadian science. In his own modest terms, he had made the NRC one of the main engines of the Canadian research system, and so, as Christine King says, helped "Canada come part of the way along the road from the ox-cart to the bulldozer".

Christine King, who was tragically killed soon after completing the manuscript of this book, attempts to tell the story of a now-powerful institution and of the men who guided it. Above all, her intention is to give some insight into the powerful personality of the NRC's leader at a time when science in Canada was in its formative years. Sad to say she succeeds only in part. Although the book is thoroughly researched and reads well, it fails to convey either a rounded picture of Steacie's character or the actual tensions between science and government that affected his ambitions and directed his choices (and that still exist in Canada today). To some extent, this is the consequence of the style of the book. Scientific biographies such as this tend to portray the protagonist in an heroic light, blurring the background of other personalities and the politics which are an essential part of the overall picture. Nonetheless Dr King's contribution is to recall an important individual at an important time in Canadian history, and for that her book is to be welcomed. ☐

John de la Mothe is in the Graduate Faculty of Administration, University of Ottawa, 275 Nicholas Street, Ottawa, Canada K1N 6N5.

- Volume 1 in the series *Aperiodicity and Order* was reviewed in *Nature* earlier this year (**338**, 550; 1989). Academic Press has now published the second volume, *Introduction to the Mathematics of Quasicrystals*, which, like the first, is edited by Marko V. Jarić. Price is $59.50, £42.50.

BOOKS FOR THE CELL BIOLOGIST FROM WILEY

Complex Organismal Functions

Integration and Evolution in Vertebrates

Edited by D.B. WAKE, University of California, USA, and G. ROTH, University of Bremen, West Germany

One of the greatest challenges in modern biology is to understand how complex and integrated systems evolve. The special interest in this topic comes from the necessity to maintain function in a highly integrated system, tuned by natural selection to high operational efficiency, while at the same time the system changes, often in dramatic ways. This book will focus in organismal approaches that take full cognizance of the total function of organisms as their populations evolve. This approach will take full account of systems of historical, constructional and functional constraints, as well as opportunities for directional evolution provided by the organismal genetic and ecological context.

Molecular Control of Haemopoiesis

Ciba Foundation Symposium 148

Chairman: D. METCALF

The many different kinds of blood cells are derived from multipotential stem cells that are induced to differentiate into one or another cell type by the action of regulatory proteins or growth factors. This symposium describes how the binding of these proteins to specific receptors causes changes in gene expression in the nucleus and in the activity of certain enzymes in the cytoplasm, thereby committing the cell to a particular developmental pathway. The haemopoietic growth factors interact with other families of known cytokines, particularly the interleukins; the role of these mutual influences in normal cells and in blood disorders, such as leukaemia, is discussed. This book includes reports on the progress of several clinical trials and discussion of future possibilities.

Methods for the Microbiological Examination of Fish and Shellfish

Edited by B. AUSTIN and D.A. AUSTIN, both of Heriot-Watt University, Edinburgh, Scotland

Dealing with the practical as opposed to the theoretical aspects of microbiological techniques, this timely book descibes methods for the isolation and characterisation of bacteria, fungi, protozoa and viruses from fish and shellfish. Highlighting the currently popular serological techniques, all the up-to-date methods used in fisheries microbiology are discussed.

Written by experts in the field with many years of practical experience, the plethora of techniques published in diverse journals are discussed and the methods relevant to fish (and shellfish) disease diagnosticians presented.

Electric Fields in Vetebrate Repair

Natural and Applied Voltages in Vertebrate Regeneration and Healng

by R.B. BORGENS, K.R. ROBINSON, J.W. VANABLE, JR, and M.E. MCGINNIS, all of Purdue University, USA

Provides readers with a solid understanding of all major model systems in the study of regeneration and healing through electrical applications. This complete overview includes a concise introduction to the topic, as well as detailed technical evaluations, and discussion of the biology of each model system. The authors examine, as well, the diverse medical applications of this growing body of research knowledge, reflecting the view that the application of our understanding of the electrophysiology of development, regeneration, and repair may well be one of the next great areas of expansion in applied medical science.

Metal Ions and Bacteria

Edited by T.J. BEVERIDGE, College of Biological Science, University of Guelph, Ontario, Canada, and R.J. DOYLE, Health Science Center, University of Louisville, Kentucky, USA

Provides a comprehensive treatment of the interactions of metals with bacteria, a subject of interest in medicine, toxicology, extraction of metals, mineral cycling and microbiology. It outlines the diversity of these interactions, their importance to bacteria and humans, and the global scale of the reaction products. Topics include the use of microbes to immobilize toxic heavy metals, natural biological metal chelators, and the impact of the biosphere of mineral production and cycling.

T Cells

by M. FELDMANN, Charing Cross Sunley Research Centre, J. LAMB, Hammersmith Hospital, London, UK, and M.J. OWEN, St Bartholomew's Hospital, London UK

T lymphocytes are the most important cells involved in immune regulation. It is not possible to understand immunology without understanding T cells and this book is the only one devoted solely to the subject. The focusing of this book on T cells makes possible a much deeper coverage than in books covering a greater span of immunology. A particular strength is to have both the basic physiology and cell biology of T cells in the same book as the discussion of the role of T cells in a variety of bacterial, viral and parasitic disease.

G-proteins as Mediators of Cellular Signalling Processes

Volume 1

Edited by M.D. HOUSLAY and G. MILLIGAN, Department of Biochemistry, University of Glasgow, UK

The guanine nucleotide binding proteins (G-Proteins) are a pervasive family of proteins which can bind and hydrolise GTP. The identification, analysis and functioning of this rapidly expanding family has involved techniques ranging from biochemical analysis to those involving cellular and molecular biology. This work by acknowledged experts in the field charts the progress of our understanding of this pivotal field from the discovery of the importance of a GTP-Binding protein in the regulation of adenylate cyclase to the present work on specific G-Proteins regulating visual transduction olfaction.

Photosensitizing Compounds: Their Chemistry, Biology and Clinical Use

Ciba Foundation Symposium 146

Chairman: T.J. DOUGHERTY

Certain organic compounds can become toxic to biological tissue when activated by light. Such toxicity can have important applications in medicine if the locus of the toxic effect can be controlled precisely, e.g. to a tumour. The basic biology of the toxic effects is not yet fully understood, and the clinical status of phototherapy is confused. This symposium brings together chemists, biologists and clinicians to discuss the current status of photochemical therapies. Consideration is given to the basic chemistry of the sensitizing compounds, their biological effects, and potential clinical applications.

BBA

Write for your personal copy of our Cell Biology catalogue!

Biochimica et Biophysica Acta ***molecular cell research***

The BBA, divided into nine sections, Bioenergetics, Biomembranes, Gene Structure and Expression, General Subjects, Lipids and Lipid Metabolism, Molecular Cell Research, Protein Structure and Molecular Enzymology, Reviews on Biomembranes and Reviews on Cancer, is the most wide-ranging, comprehensive sectional biochemical journal available today.

The BBA Molecular Cell Research section's main focus is on

- **Intact cellular studies at the molecular level**
- **Hormone and neurotransmitter action**
- **Cell regulation**
- **Molecular endocrinology**
- **Second messengers**
- **Intracellular trafficking**
- **Receptors, receptor regulation, -structure and receptor - mediated endocytosis**
- **Transmembrane signalling systems and protein phosphorylation**
- **Whole cell/whole tissue spectroscopy**

The section now also includes the subsection *Hormone and Neurotransmitter Action*, and fully covers recent developments in molecular mechanisms of the biochemistry and biophysics of whole cells.

An analysis of geophysical experiments to test Newton's law of gravity

R. L. Parker & M. A. Zumberge

Institute of Geophysics and Planetary Physics, Scripps Institution of Oceanography, University of California, San Diego, La Jolla, California 92093, USA

Signals reported as evidence for a non-newtonian 'fifth' force at a North Carolina television tower and elsewhere can be explained in a conventional way by postulating small density variations underground. The assumptions employed in earlier analyses which pointed to a failure of the inverse square law are examined and found to be difficult to justify.

THREE recent geophysical experiments to test Newton's law of gravity rely on gravity measurements made along a vertical path: in a 1,000-m deep mineshaft at the Hilton mine, Queensland, Australia[1-3]; on a 600-m television mast, the WTVD tower near Raleigh, North Carolina, USA[4,5]; and in a 2,000-m borehole into the Greenland ice cap, at the Dye-3 radar station[6]. According to classical potential theory, the values obtained on the vertical profile should be exactly predictable from other gravity observations made in the vicinity and, in the case of the underground experiments, knowledge of the density around the shaft. But it has been consistently asserted that prediction and measurement fail to coincide, and this has been taken as strong evidence for the necessity of a small modification to the inverse square law, along the lines called for by a quantum theory of gravity[7] or by introducing a totally new force of nature[8]. The predictions, however, depend on some assumed model of the gravity to interpolate between the survey points. The best calculations so far[5] draw on an unverifiable statistical model. We offer here an alternative test based on the range of permitted densities encountered in the Earth. We apply the test to the television tower experiment, and we show that conventional physics can account for the observations. The same conclusion holds for the Greenland experiment[6]. We are unable to carry out a comparable test for the Australian experiment[2,3] because the original survey data are proprietary; in any case, correction in a mine experiment would require downward continuation, which is intrinsically unstable. We conclude that the present collection of geophysical experiments provides no compelling evidence for discrepancies in the inverse square law of gravity.

Predicting gravity on a vertical profile

The value of the acceleration due to gravity, g, near the Earth's surface is governed by the Earth's rotation and its mass distribution. Traditionally geophysicists correct gravity observations for the Earth's rotation and the attraction of a model Earth; what remains is the sum of the attractions from nearby topography, from density variations in the underlying rock and, for mine and borehole observations, from the surrounding rock. In the case of underground measurements, when the density of the local material is accurately known, its attraction can also be removed. Having been corrected in this way, the gravity field obeys Laplace's equation. According to potential theory[9], the field away from the Earth's surface can then be predicted perfectly if the field is known everywhere on the surface, either by upward continuation for values above the surface, or analytic continuation for those below it.

In practice, exact prediction cannot be made with potential theory: in addition to the inevitable noise in the measurements, one must contend with the need to evaluate an integral that demands knowledge of the field at every point on the surface, not just at the observation sites; different modes of interpolation must lead to different results. Because the prediction from the surface field is inexact, one cannot decide whether or not it is in agreement with the observed value (and so test Newton's law) unless it is accompanied by an estimate of accuracy; this need is particularly acute in the case of downward continuation, which is a well-known example of an ill-posed problem[10,11]. An uncertainty estimate requires a characterization of the gravity field between the measurement sites; without it any gravity value on the vertical path is compatible with every finite surface survey. To see this, imagine expanding the gravity field in a basis of harmonic functions, such as the Fourier-Bessel set used by Romaides *et al.*[5] in their second method of prediction. If enough basis functions are included, one can always find a model field simultaneously in perfect accord with the surface data and the vertical-profile data by incorporating the tower values into the data set and fitting them rather than predicting them. Incidentally, this example illustrates why the prediction of the Fourier-Bessel expansion cannot be equipped with a satisfactory uncertainty estimate: any anomaly can be matched perfectly. Such a procedure, however, runs the risk of generating fields with wild oscillations away from the sample points, but as we shall show, such bad behaviour is not a necessary feature of models satisfying both tower and surface observations in this case.

The first method of analysis of Romaides *et al.*[5] is an example of upward continuation, in which the introduction of an explicit-field model enables the authors to compute uncertainties. They use least-squares collocation (LSC) to predict the values of g along the tower. In LSC, the gravitational field is taken to be the realization of a homogeneous, isotropic statistical process[12]. The estimated power spectrum of the process provides the necessary information about the behaviour of the gravity field between the survey sites. Thus, the predictions of LSC depend not only on the correctness of Newton's law but also on the validity of an elaborate statistical model. As the predictions fail to match the observations, logic dictates that one (or both) of these assumptions must be wrong. To claim that the failure impugns the inverse square law is to regard the statistical model as unassailable. Yet one cannot verify objectively the applicability of a statistical theory of stochastic processes to an object like the Earth's gravity field, which has only one realization. Moreover, it is self-evident that the required spatial homogeneity fails drastically on scales longer than 100 km, as the site is on the boundary of two quite different geological provinces, a major batholith to the north-west and coastal sedimentary sequences to the south-east. Furthermore, as we shall show, there are reasonable (but presumably nonstationary) classical surface fields consistent with the g-values on the tower. We therefore believe that there is no compelling reason to place greater confidence in the statistical model than in the inverse square law.

The second method given in ref. 5 for upward continuation, expansion in a Fourier-Bessel series, cannot be regarded as providing reliable confirmation of their LSC results because, as we mentioned, the uncertainty of its results is uncontrolled.

An alternative test

We propose an alternative strategy, based on the investigation of the field sources—that is, the density distribution in the

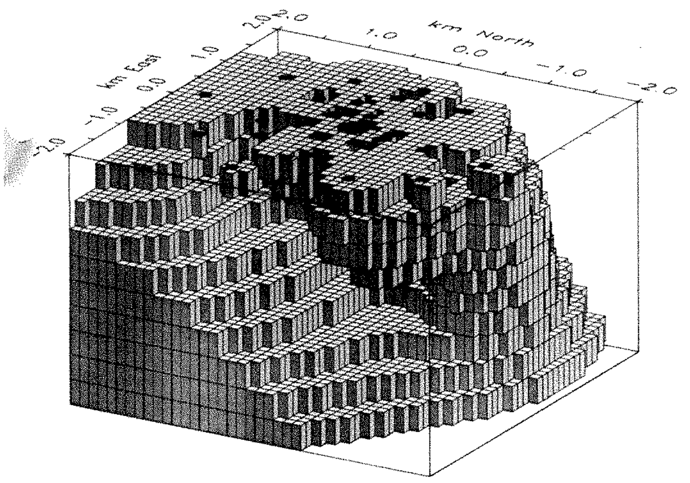

FIG. 3 One possible mass distribution accounting for the Bouguer-corrected data of Fig. 2 and the seven data shown in the topmost curve of Fig. 1. The density of the shaded cells is 0.17 g cm^{-3} less than that of the host rock. The ideal-body inversion fitted 54 gravity observations using 16,000 cells and required 20 min on a Cray XMP computer.

anomalous vertical gradient of 2 mGal km^{-1} reported in ref. 1. If variations are confined to lie below 1,500 m depth, in a volume not subjected to extensive sampling[2], then a density contrast of 0.12 g cm^{-3} is sufficient to produce the observed effect to an accuracy of ~0.05 mGal. The strata of the region show jumps in density that are larger than this by a factor of 2.5 (ref. 2) and hence such a magnitude is not unreasonable. Admittedly, in this calculation we cannot reconcile our model field with the surface survey because the latter is not available; the inclusion of such observations could make a crucial difference. The only published attempt[3] to incorporate that essential information into the analysis has been an estimate of the vertical gradient of g at the surface by means of an integral; values down the shaft and the associated uncertainty estimates have not yet been published.

Application to the tower experiment

Calculation 1. According to ref. 5, the differences between the LSC predictions and the observed values on the tower are due to a small, non-newtonian force. Using ideal-body theory we found the smallest density perturbation required underground to reproduce, by newtonian attraction, the supposedly non-newtonian field. To satisfy the observational constraints, the model produces an attraction that is zero (within 0.005 mGal) at the surface sites of ref. 5 and closely matches the discrepancies on the tower; see Fig. 1. The density contrast needed is only 0.09 g cm^{-3}. In other words, we have found a distribution of mass that accounts for the anomaly on the tower without disturbing the ground observations. It should be understood that this density perturbation is in addition to the density variations implicitly demanded by the LSC analysis. Because of the non-uniqueness of the inverse problem, our model is just one of an infinite-dimensional family of quite different distributions with approximately the same magnitude, each capable of explaining the observations with Newton's law. The fact that the additional density changes are so small makes the demand for new physics unwarranted; had density variations of 1 g cm^{-3} been required, most geologists would have found that improbable.

Calculation 2. In their calculations, Romaides *et al.*[5] upward-continued the observations corrected only for elevation and Earth rotation (the free-air anomalies[18]). Bartlett and Tew[19] point out that short-wavelength gravity signals due to the local topography may not be adequately sampled in the surface gravity survey, with the consequence that the upward-continued field could be biased. In our second calculation, we included corrections for the attraction of the topography (full Bouguer corrections[18]). The removal of the effect of the surface attractions from the observations on the tower gave rise to an important result: the corrected field has an almost exactly constant vertical gradient (Fig. 1). The obvious interpretation of such a field is that it is the natural vertical expression of the regional Bouguer anomaly with its deep origin, free of any controversial aspects whatever. Near geological bodies one expects the horizontal and vertical gravity gradients to be quite similar in magnitude. Horizontal Bouguer gradients in the region (Fig. 2) are typically ~1.5 mGal km^{-1}, caused by the Northeastern Piedmont batholith in contact with the Coastal Plain deposits[20].

We then constructed an underground mass distribution consistent with the fully corrected gravity measurements. An ideal-body model of the Bouger anomaly verifies the simple picture above: we find a large block of material extending to depths of 2.5 km with a density contrast of -0.17 g cm^{-3} (see Fig. 3). The surface observations were fitted to within 0.1 mGal; a larger tolerance must be allowed as additional uncertainties have been introduced with the Bouguer correction from the unknown variation of soil cover thickness and imprecise knowledge of the density of the surface rock. Our model produces an interpolating harmonic field just like the expansion described earlier; evaluation on surface profiles around the tower show the interpolating field to be free of wild oscillations and to lie generally within 1 mGal of the mean regional gradient. This is to be expected considering the low density of the disturbing underground mass.

For computational reasons, both of the ideal-body calculations were limited to a region of ~2 km in radius, centred on the tower. Because of this the attraction of the finite ideal body caused an artificial gravity offset in the data near the tower relative to the distant data; this offset was 1.7 mGal for calculation 1. We found that, because they were so widely spaced, the more distant data could be offset as well by appropriate emplacement of compact masses (of ideal-body density) that had insignificant effects on the gravity values within 2 km. Because such low-density masses can produce a constant offset in the outer data without significantly affecting the inner data, it was unnecessary to include the distant data in the ideal-body calculations.

The more significant result of calculation 2 was not the ideal body itself but the intermediate result needed to obtain it; that is, the correction for terrain effects which removed the curvature in the anomaly. The ideal body in our second calculation provides an illustration of the kind of massive density anomaly required to produce large regional gravity gradients. Including a larger region in the analysis might in fact require a larger density (and would certainly require a larger computing facility) to account for the ground and tower observations, because of the Bouguer anomalies that exist in the region. The results of our first calculation, however, assure us that the increase in density would be only slight.

Conclusions

In summary, we believe that there is no compelling evidence for non-newtonian long-range forces in the three most widely cited geophysical experiments; in two of them, the Greenland experiment and the North Carolina television-mast experiments, we have shown that the gravitational fields of underground density variations with plausible magnitudes can reproduce the effects formerly ascribed to new forces. The Australian experiment has not been subjected to a sufficiently stringent test. It is important to understand that we have not shown the inverse square law to be accurate on the scales of these experiments; we have only shown that the case for its failure has not been established. More sensitive geophysical experiments might still uncover some inadequacy. Two possibilities stand out as particularly worth pursuing: an experiment on a tower that stands on a level sedimentary plane, and a marine experiment in very deep water[21]. □

[†] Division of Regulation of Macromolecular Function, Institute for Protein Research, Osaka University, 3-2 Yamadaoka, Suita 565, Japan

Cloning and expression of functional P_{400} protein from cerebellar Purkinje neurons shows that this protein is a receptor for inositol 1,4,5-trisphosphate, a second messenger that mediates the release of intracellular calcium.

THE mouse cerebellum contains five different neuronal cell types. One of these, the Purkinje cell, is considered to play a central role in information processing, because it is the target of all inputs and is the only neuron that sends outputs from the cerebellar cortex. In the course of a study on cerebellar ataxic mutant mice, a membrane glycoprotein P_{400} was found to be enriched in Purkinje cells from normal mice but reduced in the cerebella of Purkinje-cell-deficient mutants[1-3]. The P_{400} protein has a relative molecular mass (M_r) of 250,000 (250K)[1,3] and is phosphorylated[4] in a cyclic AMP-dependent manner[5]. A pulse labelling study with [^{14}C]leucine showed that it is synthesized in the cerebellum[4]. We have solubilized and purified P_{400} protein from mouse cerebella and obtained three independent anti-P_{400} monoclonal antibodies[6,7]. Immunohistochemical study of the cerebellum shows that P_{400} protein is localized to the dendrites and axons, as well as cell bodies of Purkinje cells[7], where immunoreactivity to the protein is localized on the plasma membrane, endoplasmic reticulum (ER) and postsynaptic density of Purkinje cells[7]. Western blot analysis in several other tissues reveals the presence of a small amount of P_{400} protein[6], indicating that it plays an essential part in a general membrane function that is increased in cerebellar Purkinje cells.

Inositol 1,4,5-trisphosphate ($InsP_3$) is known to play an important second messenger role in many cells, including neurons[8]. Recently Supattapone *et al.*[9] purified an $InsP_3$-binding protein (M_r, 260K) from the rat cerebellum. This receptor is a glycoprotein capable of binding to concanavalin A and is a substrate for cAMP-dependent protein kinase[9,10]. They also showed that [^{3}H]$InsP_3$-binding activity is very much higher in the cerebellum than in any other brain area[11,12], and is selectively localized to Purkinje cells[12]. From its characteristics (M_r, glycosylation, cAMP-dependent phosphorylation and tissue concentration), they propose that this receptor protein is identical to the three other cerebellar phosphoproteins—including P_{400}—that have been recently described[9,13,14]. We have also confirmed that P_{400} protein is identical to the $InsP_3$ receptor protein[15].

We report here the cloning of the P_{400} complementary DNA together with its amino-acid sequence deduced from the cDNA sequence[16]. Expression of P_{400} messenger RNA was examined in the cerebellar mutant mice by northern blot analysis and was localized by *in situ* hybridization in cerebellar sections. We demonstrate that NG108-15 cells (mouse neuroblastoma/rat glioma hybrids) transfected with P_{400} cDNA express binding sites for $InsP_3$ and that the predicted structure of the P_{400} protein resembles that of the ryanodine receptor[17], which mediates Ca^{2+} release from the sarcoplasmic reticulum (SR) of skeletal muscle during excitation–contraction coupling.

Cloning of P_{400} cDNA

Two mouse cerebellum cDNA libraries, synthesized by priming with random hexamer or oligo(dT), were constructed in phage-λgt11 expression vectors (Fig. 1). The library was first screened with the three anti-P_{400} monoclonal antibodies (4C11, 10A6 and 18A10)[6,7]. Of 21 immunopositive candidates obtained, five were selected for further study on the basis of their strong immunoreactivity in western blot analysis (data not shown). In northern blot analysis of mouse cerebellar poly(A)$^+$RNA, the cDNA inserts in all five independent clones hybridized to an mRNA of $\sim$10 kilobases (kb), which is long enough to encode the P_{400} protein (data not shown). To obtain more complete clones, we rescreened both the random-primed and oligo(dT)-primed libraries by plaque hybridization with the ^{32}P-labelled cDNA inserts. Two types of clone were obtained; these differed at the polyadenylation sites by 800 bases.

The complete cDNA sequence was determined[16] by sequencing the 12 clones listed in Fig. 1*a*. There is a single large open reading frame[16]. Although the neighbouring sequence (CGGACATGT) of the first ATG shows only modest similarity to the initiation consensus sequence (CCA/GCCATG(G))[18], it is closer to the consensus sequence than the sequence (ACAAAATGT) surrounding the second ATG. The open reading frame continues for 8,247 bases when an in-frame TAG termination codon occurs at nucleotide position 8,248 from the first ATG. This frame was confirmed by sequencing the fusion points between the β-galactosidase gene and cDNA inserts in the five immunopositive clones tested. The sequence of the long type cDNA is 9,871 nucleotides, consisting of a 328 base pairs (bp) 5′ untranslated region, a 8,247 bp coding region and a 1,296 bp 3′ untranslated region which includes a polyadenylation signal (AATAAA) 14 bp upstream of a 23 base poly(A) tract. The short type cDNA is 9,071 nucleotides long, differing only in the 3′ untranslated region (496 nucleotides, including AATAAA 12 bp upstream of a 23-base poly(A) tract). It seems that the long cDNA was derived from the principal transcript, as five out of the seven 3′ clones, primed by oligo(dT), were of the long type.

Structure of the P_{400} protein

On the basis of the cDNA sequence, the P_{400} protein is predicted to comprise 2,749 amino acids and have an M_r of 313K. Although glycosylation is known to contribute to the molecular weight only slightly, this is somewhat greater than the SDS-gel electrophoresis estimate of 250K. This discrepancy may be accounted for by post-translational proteolytic processing, or aberrant electrophoretic migration due to its large size. The amino-acid composition of the predicted polypeptide agrees with that obtained by amino-acid analysis of hydrolysed P_{400} (data not shown). From sequence analysis of immunopositive clones, the amino-acid sequences containing epitopes for the antibodies 4C11, 10A6 and 18A10 are localized from position 679–727, 943–1,237 and 2,648–2,749 (C-terminal end), respectively (Figs 1*b* and 2*a*).

A hydropathy profile of the protein sequence shows the existence of several stretches of hydrophobic amino acids, which could represent multiple membrane-spanning sequences (Fig. 1*b* and 2). Although P_{400} is thought to be an integral membrane protein[6,7], it lacks a definable signal sequence with a hydrophobic stretch at the N-terminus, which indicates that an N-terminal hydrophilic region is exposed on the cytoplasmic face of the membrane[17,19]. By scanning the sequence for hydrophobic stretches[20], nine candidates membrane-spanning regions were detected (a–i in Fig. 2*a*). Preliminary results from an electron microscopy study of metallo-labelled antibodies indicate that the epitopes for 4C11 and 10A6, which recognize the N-terminal region and the central region, respectively, are located to the cytoplasmic side, whereas an 18A10 epitope, which recognizes the C-terminus, is on the luminal side of the ER (N.M. *et al.*, unpublished data). The first two segments (a and b) are, therefore, unlikely to be membrane-spanning. Of the seven remaining segments (c to i), clustering in the C-terminus from amino-acid positions 2,276 to 2,589, all (or some) of the segments presumably form transmembrane α-helices and may traverse either the ER or plasma membranes of cerebellar Purkinje cells an odd number of times (see Fig. 2 legend). Consequently, the large hydrophilic N-terminal domain is exposed on the cytoplasmic face of the membrane, whereas the short C-terminal domain is oriented towards the ER lumen or outside the cell (Fig. 2*b*).

The protein has 21 consensus sequences for *N*-linked glycosylation. Most of these, however, are not involved in glycosylation, because digestion of P_{400} protein with endo-β-*N*-acetylglucosaminidase F causes only small changes in the electrophoretic mobility[6]. Partial digestion of P_{400} by *Staphylococcus aureus* V8 protease generated a polypeptide of M_r ~40K, possessing both binding activity to concanavalin A and immunoreactivity with the C-terminal-specific antibody 18A10 (data not shown). This result suggests that at least the C-terminal region is glycosylated. Additionally, the large cytoplasmic domain contains two sites that could act as targets for serine

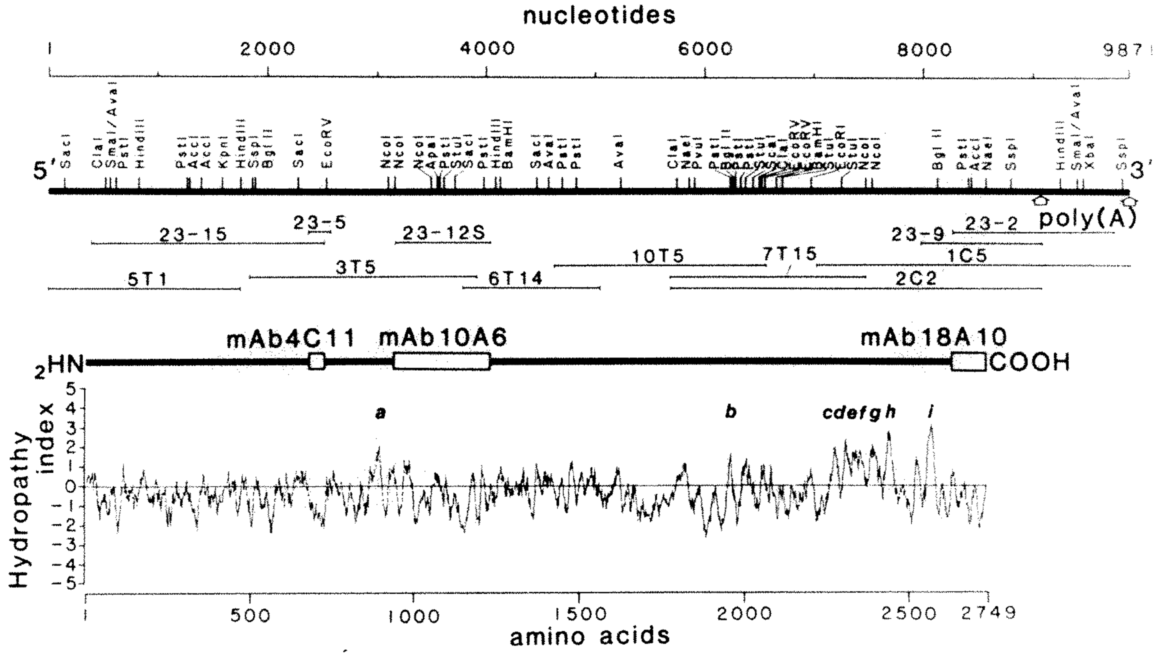

FIG. 1 *a*, Restriction map of the P_{400} cDNA clones. The positions of the 12 overlapping clones are indicated. Two open arrows point to the polyadenylation sites. *b*, Hydropathy plot of protein-coding region. Three open boxes represent the regions containing epitope sequences for monoclonal antibodies (mAb) 4C11, 10A6 and 18A10. Hydrophobic segments (a to i) are indicated.

METHODS. Poly(A)$^+$RNA was isolated from cerebella of two- to three-week-old mice (ICR) by the guanidinium-CsCl method[36], followed by purification by oligo(dT)-cellulose chromatography[36]. The cDNA was synthesized using a random hexamer or oligo$(dT)_{12-18}$ as primers essentially as described previously[37]. For random-primed cDNA synthesis, poly(A)$^+$RNA with a sedimentation coefficient of more than 23S in sucrose gradients (15–30% sucrose gradients spun at 30,000 r.p.m. in a Beckman SW41Ti rotor for 16 h at 25 °C) was used. Both random-primed and oligo(dT)-primed cDNAs were ligated in the lambda-gt11 expression vector[38]. First, the random-primed library was immunoscreened for the production of fusion protein containing putative P_{400} epitopes in the host *E. coli* strain Y1090r$^-$ using monoclonal antibodies[38,6]. At subsequent stages, both the random-primed and oligo(dT)-primed libraries were screened by plaque hybridization using the ^{32}P-labelled cDNA inserts derived from immunopositive clones (clone 23-2, 23-5, 23-9, 23-12S and 23-15 in Fig. 1*a*). The cDNA inserts were subcloned into pUC118 or pUC119 (ref. 39) and sequenced[16] by the dideoxy chain termination method[40]. The hydropathy plot was computed according to Kyte and Doolittle[41]; the window size is 17 residues.

◀ FIG. 2 Predicted amino-acid sequence and structural model of P_{400} protein. *a*, The amino-acid sequence of P_{400} protein was deduced from its cDNA sequence[16] (EMBL database accession number X15373). The regions containing epitope sequences for monoclonal antibodies are shown by dashed lines. The proposed membrane-spanning sequences are represented by double dashed lines (a–i). The filled arrowheads mark the potential phosphorylation sites for cAMP-dependent protein kinase. The 3′-deletion construct shown in Fig. 5 encodes a polypeptide from the first methionine to the cysteine of position 2,215, marked with the open arrowhead. *b*, A schematic model for the topology of P_{400} protein in the membrane. A computer program (ALOM), for prediction of membrane-spanning segments[20], in the Integrated Database and Extended Analysis System (IDEAS) was used through the National Institute of Genetics (NIG) in Japan. Possibilities for membrane-spanning become confident in the following orders: segments i > h > d > g > a > c > f > e > b (peripheral:integral odds = 7.0E-07 > 8.1E-06 > 5.1E-04 > 4.5E-03 > 1.2E-02 > 3.2E-02 > 7.8E-02 > 4.0E-01 > 5.3E-01, respectively). To orient termini to opposite sides, the P_{400} protein should traverse the membrane an odd number of times. Epitopes for antibodies 4C11 and 10A6 are localized to the cytoplasmic side, indicating that segment a is not membrane-spanning. We assume, therefore, that P_{400} traverses the membrane at most seven times (c to i) and at least 3 times because of the presence of three reliable segments d, h and i with high odds. Based on this prediction and the epitope localizations, we have designed the structural model for P_{400} as a membrane-spanning protein. Putative transmembrane domains are indicated by an open box. The C-terminal domain is either located in the ER lumen or outside the cell by anchoring to the ER and plasma membrane, respectively. The regions containing epitope sequences for monoclonal antibodies are shown by dotted lines. The potential phosphorylation sites are represented by an encircled P.

phosphorylation (amino acids 1,588 and 1,755), a possibility supported by the fact that a serine residue of P_{400} protein is known to be phosphorylated in a cAMP-dependent manner[5].

P_{400} expression in Purkinje cells

In situ hybridization histochemistry clearly shows that P_{400} mRNA is localized in the perikaryon of Purkinje cells of the cerebellum (Fig. 3). We examined gene expression of P_{400} in the cerebellar ataxic mice by northern blot analysis (Fig. 4). The *staggerer* mutant Purkinje cells have a withered dendritic arbor lacking the tertiary branchlet spines that serve as the sites of synapse between the granule cells and Purkinje cells[21]. The disorder of Purkinje cells is most severe in the *Purkinje cell degeneration* (*pcd*) and *nervous* mutants, where most of these cells degenerate selectively (95–99% in *pcd*[22] and about 85% in *nervous*[23]). The cerebella of these Purkinje cell-deficient mutants contain P_{400} mRNA at extremely low levels, as expected (lanes 2, 3 and 4 in Fig. 4). On the other hand, the cerebellum of the *weaver* mutant, which lacks granule cells with no significant loss of other cerebellar neurons[24], contains an increased amount of P_{400} mRNA compared with the wild-type cerebellum (lane 4). This increase in the *weaver* mutant was also observed at the protein level[1,4] and is caused by a relative increase in the proportion of Purkinje cells in the cerebellum, due to the dearth of granule cells.

These results clearly indicate a predominant distribution of P_{400} gene expression in the cerebellar Purkinje cells. Our preliminary experiments, however, have shown that the expression of P_{400} mRNA can be detected at a level of about one fiftieth in the cerebrum and at much lower levels in other tissues (data not shown), indicating that P_{400} expression is widespread and possibly general.

$InsP_3$-binding properties

Our recent results indicate that P_{400} protein has $InsP_3$-binding activity[15]. To examine whether the P_{400} cDNA clone encodes an $InsP_3$-binding protein, we performed $InsP_3$-binding assays on protein expressed in the neuroblastoma/glioma hybrid cell line NG108-15. In the neuron-like NG108-15 cells, it is known that $InsP_3$ acts as a second messenger and transiently raises intracellular Ca^{2+} (ref. 25). This cell contains an endogenous protein immunoreactive to the anti-P_{400} monoclonal antibody 4C11 (Fig. 5*a*, lane 4). This protein cross-reacts equally with all three of our monoclonal antibodies (data not shown). It is interesting that the molecular size of the endogenous P_{400} protein

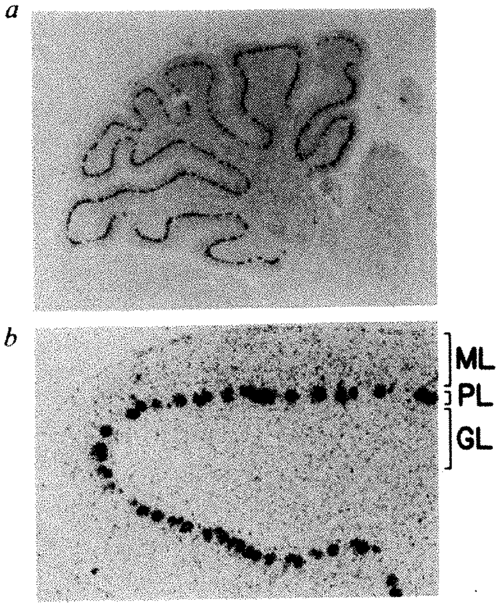

FIG. 3 Localization of the P_{400}-specific mRNA by *in situ* hybridization. *a*, Autoradiograph of a sagittal section of the cerebellum. *b*, Higher magnification of *a*. ML, molecular layer; PL, Purkinje cell layer; GL, granular layer. Sections (6 μm) in paraffin were prepared from the cerebellum of 30-day-old ICR mice. *In situ* hybridization with a random-primed ^{35}S-labelled P_{400} cDNA was as before[42].

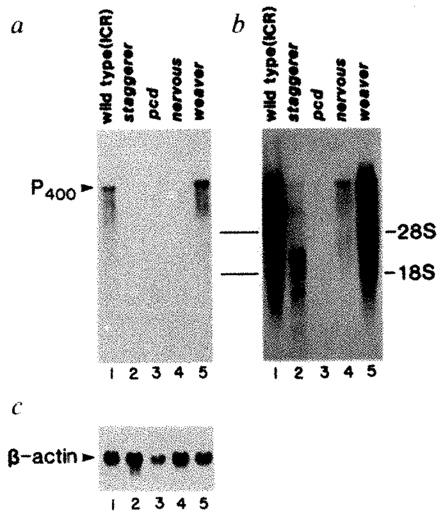

FIG. 4 Northern blot analysis of P_{400} mRNA in the cerebella of mutant mice. *a*, Wild-type ICR, lane 1; *staggerer*, lane 2; *pcd*, lane 3; *nervous*, lane 4; and *weaver*, lane 5 mice. *b*, Long exposure of the hybridization membrane in *a*. *c*, Rehybridization of the same blot in *a* with a β-actin probe to assess the relative amounts of RNA in each lane. Although an equal amount of total RNA was used, *pcd* showed a weaker signal for β-actin mRNA.

METHODS. Total cellular RNA (20 μg) from the cerebella was electrophoresed on a 1% agarose-formaldehyde gel[36], blotted to a nylon membrane (Biodyne. A, Pall) and hybridized at 42 °C for 20 h with random-primed ^{32}P-labelled P_{400} cDNA or β-actin cDNA probes (1×10^9 c.p.m. μg^{-1}, $1\text{-}2 \times 10^6$ c.p.m. ml^{-1}) in 50% formamide, 5 × Denhardt's solution, 5 × SSC, 50 mM sodium phosphate (pH 6.5), 0.1% SDS, 100 μg ml^{-1} heat-denatured herring sperm DNA and 10% dextran sulphate. The membrane was washed twice in 2 × SSC and 0.1% SDS at room temperature for 10 min, twice in 0.1 × SSC and 0.1% SDS at 65 °C for 30 min. The blot was exposed at −70 °C to X-ray film with an intensifying screen.

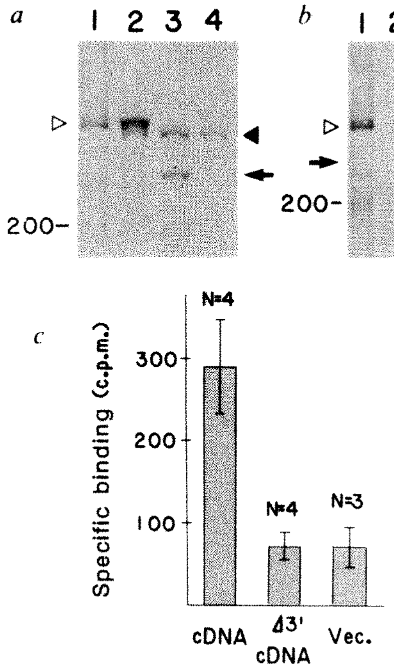

FIG. 5 Binding of $[^3H]InsP_3$ to P_{400} protein expressed in NG108-15 cells. *a*, Western blot analysis of crude membrane proteins using the anti-P_{400} monoclonal antibody 4C11. Lane 1, Microsomal proteins (5 µg) prepared from the mouse cerebellum; lane 2, crude membrane proteins (50 µg) prepared from the NG108-15 transfected with P_{400} cDNA; lane 3, 3′-deletion construct and lane 4, vector plasmid DNA. Cerebellar P_{400} protein (△); endogenous P_{400} of NG108-15 (▲); truncated P_{400} (→). The position is shown of a molecular weight marker ($\times 10^{-3}$). *b*, Western blot analysis of soluble cytosolic proteins using 4C11. Lane 1, the same as lane 1 of *a*; lanes 2 to 4, soluble cytosolic proteins (15 µg) prepared from the same cells as those in lanes 2 to 4 of *a*, respectively. *c*, Specific binding of $[^3H]InsP_3$ to crude membrane proteins prepared from NG108–15 transfected with P_{400} cDNA (cDNA), the 3′-deletion construct (Δ3′ cDNA) or vector DNA (Vec). *N* represents the number of samples tested. Results are the means ± s.e.m. of *N* samples.

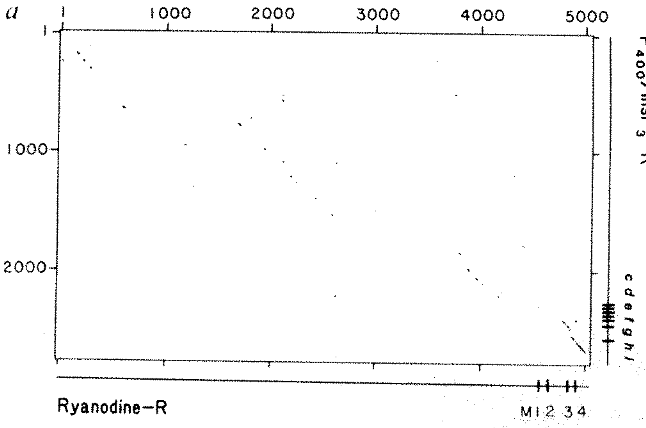
METHODS. Plasmid DNAs used for the transfection assay were constructed as follows. p*β*act-CAT9 (ref. 43) was digested with *Hin*dIII and *Hpa*I to remove the chloramphenicol acetyltransferase (CAT) sequence, treated with Klenow enzyme and dNTPs, and ligated to a *Sal*I linker (GGTCGACC). The resulting plasmid pBact-S, containing a single *Sal*I site in place of the CAT gene fragment, between the *β*-actin promoter and SV40 polyadenylation sequences, was used as a vector. To generate pBact-CI, the full P_{400} cDNA (short type in Fig. 1) was ligated to *Sal*I linkers at both ends and inserted into the *Sal*I site of pBact-S. The DNA fragment from the 5′ end to an internal *Eco*RI site (6,646 nucleotide position in Fig. 1) of P_{400} cDNA was also inserted into the *Sal*I site of pBact-S. The resultant plasmid pBact-EL2 encodes a ~252K truncated polypeptide which lacks the 534 amino acids of the C-terminal portion (Fig. 2). These plasmid DNAs were introduced into NG108-15 cells by the standard calcium phosphate precipitation technique[44]. Two days after transfection, cells were collected, washed with ice-cold TBS (Tris-buffered saline) and resuspended in ice-cold 0.25M sucrose in buffer A (10 mM Tris–HCl, pH 8.0, 0.1 mM EDTA, 1 mM PMSF, 0.01 mM pepstatine A, 0.2 U ml^{-1} aprotinin). The cells were homogenized by 10 strokes in a chilled glass-Teflon Potter homogenizer and centrifuged at 3,300*g* for 3 min at 2 °C to remove nuclei. The supernatants were recentrifuged at 95,000 r.p.m. ($393,201 \times g_{max}$) in a Beckman TLA100.2 rotor for 5 min at 2 °C. The resulting pellets and supernatants were used as crude membrane proteins and soluble cytosolic proteins, respectively. Some of the protein was used for western blot analysis[6,7]. Cerebellar microsome was prepared as described[7]. The $[^3H]InsP_3$-binding assay, using rapid centrifugation[15] for membrane fractionation or PEG precipitation for soluble fractionation[15], was performed by incubating 50 µg of the proteins in 100 µl buffer A containing 10 nM $[^3H]InsP_3$ (NEN) for 10 min at 4 °C. Nonspecific binding was determined in the presence of 1 µM cold $InsP_3$. Specific binding was defined by the subtraction of nonspecific binding, ranging from 200 to 250 c.p.m., from total binding.

in NG108-15 (lane 4) is less than that in the mouse cerebellum (lane 1). This size difference allows discrimination between cerebellar P_{400} and endogenous P_{400} in NG108-15. Scatchard analysis using $[^3H]InsP_3$ revealed that the NG108-15 P_{400} differs from the cerebellar P_{400} in having two specific binding components, of high- and low-affinity, with low capacity (A.M. *et al.*, unpublished data). In the transient assay, the P_{400} cDNA-transfected cells produced a large amount of protein immunoreactive to all three of the anti-P_{400} monoclonal antibodies (Fig. 5*a*, lane 2; immunoreaction pattern with 4C11). Both the cDNA-derived and endogenous P_{400} proteins were observed in membrane fractions, but not in soluble cytosolic fractions (lane 2 in Fig. 5*a*, *b*). In the cDNA-transfected cells, expression of the cerebellar-type P_{400} protein, derived from the cDNA, is apparently coupled with the elevation of $[^3H]InsP_3$ binding activity (Fig. 5*c*). The expressed protein displays a high affinity (K_D, 21.7 nM) and specificity for $Ins(1,4,5)P_3$ with high capacity, as does P_{400} in cerebellar microsomes[11,15] (A.M. *et al.*, unpublished data). According to our preliminary data, specific $[^3H]Ins(1,4,5)P_3$ binding of the expressed protein is competed out tenfold less by $Ins(2,4,5)P_3$ than by $Ins(1,4,5)P_3$. The potency order of competition by various inositol phosphates is: $Ins(1,4,5)P_3 > Ins(2,4,5)P_3 \geq Ins(1,3,4,5)P_4 > Ins(1.4)P_2$.$Ins(1)P$ is inactive in competition at concentrations as high as 50 µM. When transfected with the 3′-deletion construct that lacks the 3′ region encoding the 534 amino-acid residues of the C-terminus, including the putative transmembrane domains (Fig. 2), NG108-15 produced a truncated protein (~252K) immunoreactive to antibodies 4C11 and 10A6, but not 18A10. Expression of the truncated protein was not accompanied by elevation of $InsP_3$-binding activity (Fig. 5*c*). Truncated protein was observed mostly in the soluble cytosolic fraction (lane 3 in Fig. 5*b*), about 1% being found in the membrane fraction (lane 3 in Fig. 5*a*), which could be due to contamination during preparation.

These results demonstrate that the P_{400} protein encoded by our cDNA is present on membranes and does possess $InsP_3$ binding activity. The results from the transfection assay with the 3′-deletion construct reveal that C-terminal hydrophobic stretches could function as a membrane anchor, because the mutant protein accumulates in the cytoplasm. The deleted region

FIG. 6 Sequence comparison between the murine $InsP_3$-binding protein P_{400} and the rabbit ryanodine receptor. *a*. Diagonal matrix comparison using a DIAGON computer program[45] modified by Dr T. Inoue. The dots correspond to mid-points of 25-residue spans, giving a double-matching probability that the mean score is ≥1.7. Solid bars indicate possible transmembrane segments. *b*. Alignment of the amino-acid sequences. Identical residues are enclosed within solid boxes and conservative substitutions within dashed boxes. Gaps (dashes) were introduced to maximize homology. The numbers of inserted residues are indicated in parentheses. c–i, Putative P_{400} membrane-spanning regions. M1–M4, putative ryanodine receptor membrane-spanning sequences.

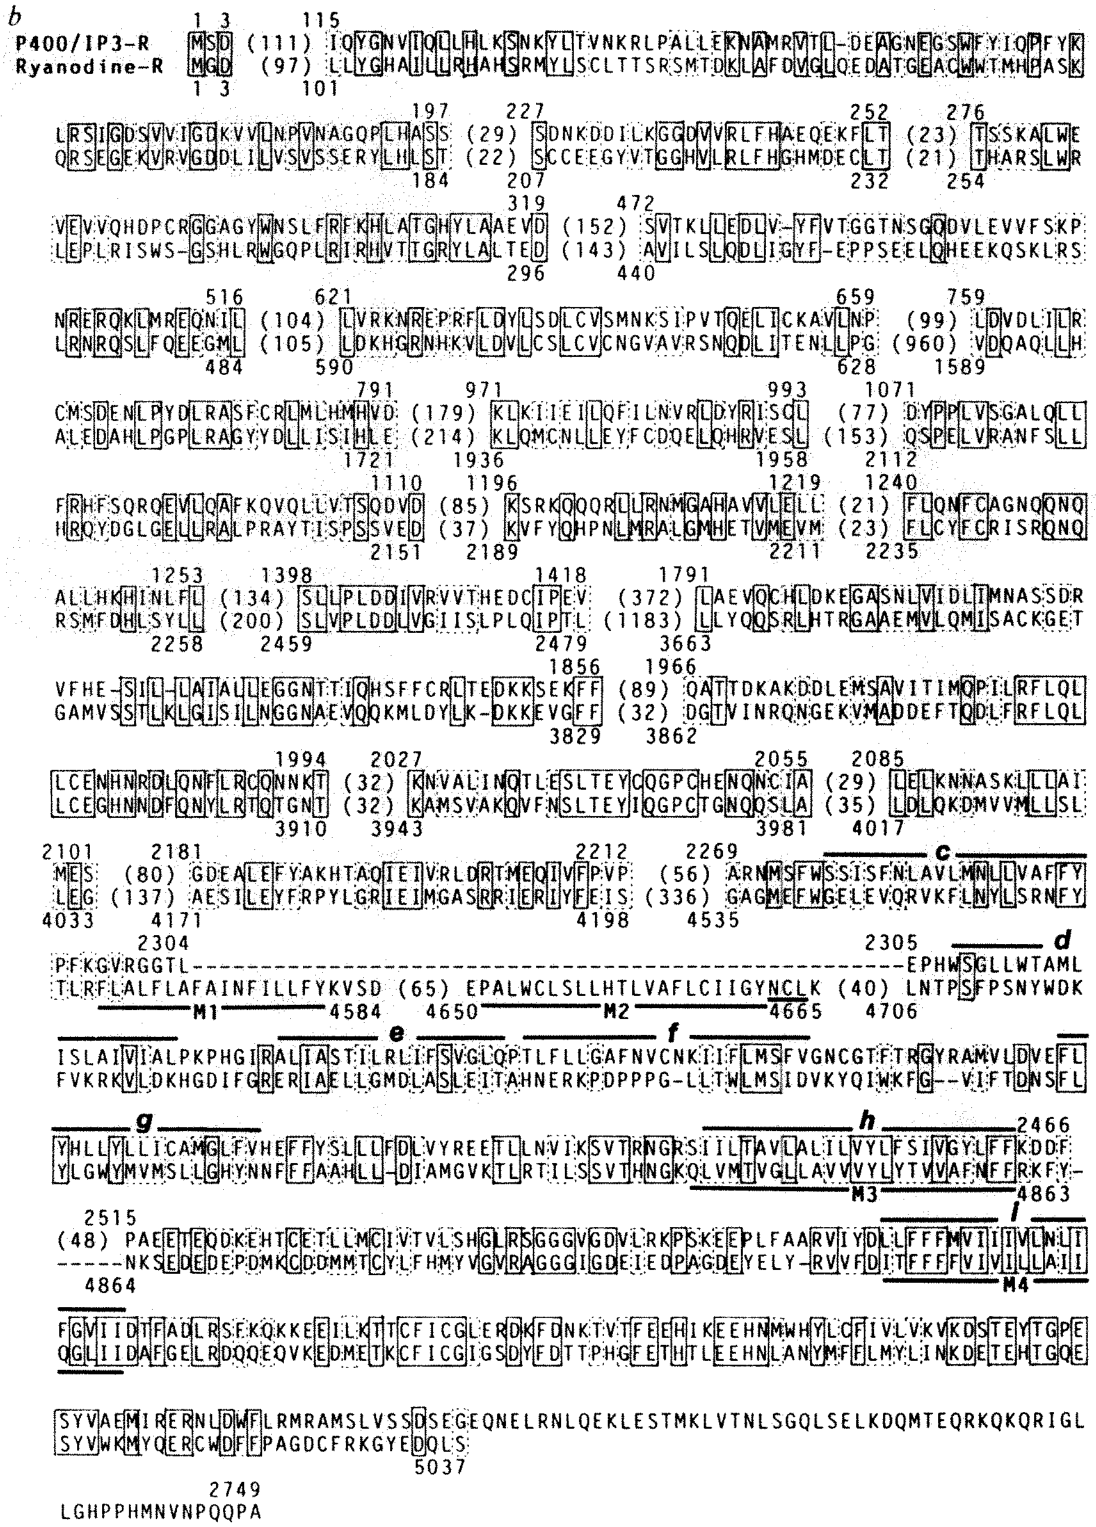


may also be responsible for $InsP_3$ binding, or may be important in forming a conformation capable of $InsP_3$ binding.

Discussion

Similar molecular features and spatial distributions suggest an identity between the P_{400} protein and the $InsP_3$ receptor/binding protein reported by Snyder *et al.*[9-12]. Recently, Nordquist *et al.*[26] isolated cDNA clones from a library of normal mouse cerebellar cDNA by differential screening with mRNA from the cerebellum of *pcd* mutant mice. We have found that one clone, PCD6, contains a 500-amino-acid sequence which has an identity with the C-terminal region of P_{400} protein, except that the leucine at residue 2,675 of P_{400} is a proline in PCD6. Distribution of PCD6 mRNA expression is also similar to that of P_{400}. These results indicate that PCD6 is a partial clone of P_{400}.

$InsP_3$ is thought to act by binding to a specific intracellular receptor, probably on a component of the ER[8] or a more discrete specialized structure, the 'calciosome'[27,28]. There are some discrepancies, however, between the subcellular localization described in our results[7] and those reported by Ross *et al.*[29]. Using polyclonal antibodies they localized the $InsP_3$ receptor to the ER, the subplasmalemmal cisternae and the nuclear membrane, but not to the plasma membrane. Our electron microscopy study using monoclonal antibody 4C11 indicates



Tyrosine phosphorylation of the fission yeast *cdc2*$^+$ protein kinase regulates entry into mitosis

Kathleen L. Gould* **& Paul Nurse**

ICRF Cell Cycle Group, Microbiology Unit, Department of Biochemistry, University of Oxford, South Parks Road, Oxford OX1 3QU, UK

The *cdc2*$^+$ protein kinase (pp34) is found to be phosphorylated on tyrosine as well as serine and threonine residues in exponentially growing *Schizosaccharomyces pombe*. At mitosis, the level of pp34 phosphorylation on both threonine and tyrosine residues decreases. The single detectable site of tyrosine phosphorylation in pp34 has been mapped to Tyr 15, a residue within the presumptive ATP-binding domain. Substitution of this tyrosine by phenylalanine advances cells prematurely into mitosis, establishing that tyrosine phosphorylation/dephosphorylation directly regulates pp34 function.

THE *cdc2*$^+$ gene encodes a 34K phosphoprotein (that is, of relative molecular mass 34,000) with protein-serine/threonine kinase activity, termed pp34, which plays a key part in regulating the eukaryotic cell cycle (reviewed in ref. 1). In the fission yeast, *Schizosaccharomyces pombe*, *cdc2*$^+$ acts at two points in the cell cycle: first at 'start' where it is required for entry into S-phase and then again in late G2 where it regulates entry into mitosis[2]. The homologue of *cdc2*$^+$ in *Saccharomyces cerevisiae*, *CDC28*, is required at 'start'[3] and possibly later in the cell cycle for mitosis[4]. A functionally equivalent and structurally similar gene has also been identified in human cells[5,6] and other organisms[7,8]. In frog[9,10] and starfish[11], pp34 is a component of maturation promoting factor, which regulates onset of meiotic and mitotic M-phase during oocyte maturation and early embryogenesis. These observations have led to the proposal that pp34 is part of a universal control mechanism regulating onset of M-phase in all eukaryotic cells[1].

Entry into M-phase is believed to be brought about by activation of pp34 protein kinase activity, which rises to a peak at M-phase in all organisms investigated[1]. In *S. pombe*, activation of pp34 requires a 56K cyclin-like protein[12] encoded by *cdc13*$^+$ (refs 13-16) and the *cdc25*$^+$ gene product[12,17,18]. Cyclins have been found physically associated with pp34 in eukaryotic cells[19-21], and there is increasing evidence that *cdc25*$^+$-like genes function in mitotic control in other organisms[22,23]. Activation of pp34 in *S. pombe* is inhibited by the *wee1*$^+$ gene product, a putative protein-serine/threonine kinase[24]. In starfish[11], frog[25,26], and mammalian cells (refs 27, 28; C. Norbury, personal communication), protein kinase activation at M-phase is associated with pp34 dephosphorylation. Anti-phosphotyrosine antibodies have been used to demonstrate that in frog[25] and mammalian cells[28] dephosphorylation occurs on tyrosine and this has been confirmed in mammalian cells by phosphoamino-acid analysis (ref. 28; C. Norbury, personal communication). A role for tyrosine phosphorylation in regulating pp34 is of particular interest, given the importance of tyrosine-protein kinases in the control of mammalian cell growth. However, in both *S. pombe*[29] and *S. cerevisiae*[30], pp34 phosphorylation levels have been reported not to change during the cell cycle and phosphoamino-acid analyses have failed to detect phosphotyrosine in the protein[31,32]. Indeed, it is not even clear if tyrosine phosphorylation of any protein occurs in unicellular eukaryotes such as yeast, although low levels of phosphotyrosine[33] and protein-tyrosine kinase activity[34] in *S. cerevisiae* have been reported.

In this paper we establish that *S. pombe* pp34 is phosphorylated on tyrosine as well as on serine and threonine, the first demonstration of phosphotyrosine in this unicellular organism. Using highly synchronized cultures, we show that dephosphorylation of tyrosine and threonine residues occurs as *S. pombe* cells enter mitosis. We have localized the single detectable site of tyrosine phosphorylation in pp34 to Tyr 15, a residue within the proposed ATP-binding domain. Replacement of this tyrosine with phenylalanine abolishes tyrosine phosphorylation of pp34 and leads to premature advancement of cells into mitosis. This demonstrates that tyrosine phosphorylation/dephosphorylation of pp34 directly regulates entry of cells into mitosis.

Dephosphorylation during mitosis

To examine the phosphorylation state of pp34, we used an antiserum, hereafter referred to as PN24, raised against a peptide corresponding to the C-terminal seven amino acids of the *cdc2*$^+$ gene product[29]. Immunoprecipitation from ^{32}P-labelled wild-type *S. pombe* (strain 972) with PN24 revealed a major 34K band following electrophoresis and autoradiography (Fig. 1*a*, lane 1). The specificity of this reaction was demonstrated by the ability of the C-terminal peptide to block immunoprecipitation of pp34 when pre-incubated with the antiserum (Fig. 1*a*, lane 2). Also, one-dimensional peptide mapping of the immunoprecipitated 34K protein in comparison with bacterially produced pp34 using the chemical cleavage reagent, *N*-chlorosuccinimide[5] established that the immunoprecipitated protein was the product of the *cdc2*$^+$ gene (data not shown).

The relative level of pp34 phosphorylation at various points during the cell cycle was examined by immunoprecipitating pp34 from ^{32}P-labelled temperature-sensitive cdc strains arrested at their nonpermissive temperatures. Specifically, we used the *cdc25*-22 and *cdc13*-117 strains to block cells either in late G2 or in mid-mitosis, respectively. There was four times more ^{32}P in pp34 isolated from cells blocked in late G2 than there was in pp34 immunoprecipitated from cells arrested in mitosis (Fig. 1*b*, lanes 1 and 2). When isolated from exponentially growing cells, pp34 contained an intermediate level of ^{32}P (data not shown). Consistent with the lower ^{32}P content of pp34 in mitotically arrested cells, a decrease in pp34 phosphorylation was observed as cells entered mitosis when released from a late G2 block (Fig. 1*c*).

Tyrosine phosphorylation

Immunoprecipitates of pp34 from various ^{32}P-labelled cells were partially hydrolysed with acid to determine their phosphoamino-acid composition. All three phosphoamino acids were found in pp34 from exponentially growing cells (Fig. 2*a*). Phosphothreonine was most prominent, phosphotyrosine somewhat less abundant, and phosphoserine was barely detectable. The phosphoamino-acid content of pp34 from cells blocked in late G2 was slightly different in that phosphoserine was not detectable even in very long exposures and the level of phosphotyrosine was roughly equivalent to the level of phosphothreonine (Fig. 2*b*). The ratio of phosphothreonine to phosphotyrosine in pp34 was nearly 1 : 1 in cells blocked in mitosis (Fig. 2*c*) or released from a G2 block for 30 min (Fig. 2*d*), when overall phosphorylation is reduced. This indicates that dephosphorylation of both threonine and tyrosine residues occurs as cells traverse the boundary between G2 and M-phase.

---

* To whom correspondence should be addressed.

The phosphotyrosine content of pp34 as cells entered mitosis was also examined with anti-phosphotyrosine antibodies. We immunoprecipitated pp34 from unlabelled *cdc25*-22 cells arrested in late G2 at 36 °C and released for 30, 45 and 60 min by shifting to the permissive temperature of 25 °C. The amount of phosphotyrosine in pp34 decreased 4-5-fold within 30-45 min of release, whereas the level of protein did not change appreciably (Fig. 3*a, b*). This decrease in reactivity with anti-phosphotyrosine antibodies occurred with the same kinetics as the decrease in overall ^{32}P content of pp34 observed in [^{32}P]-orthophosphate labelling experiments (compare Fig. 1*c* with Fig. 3*a*).

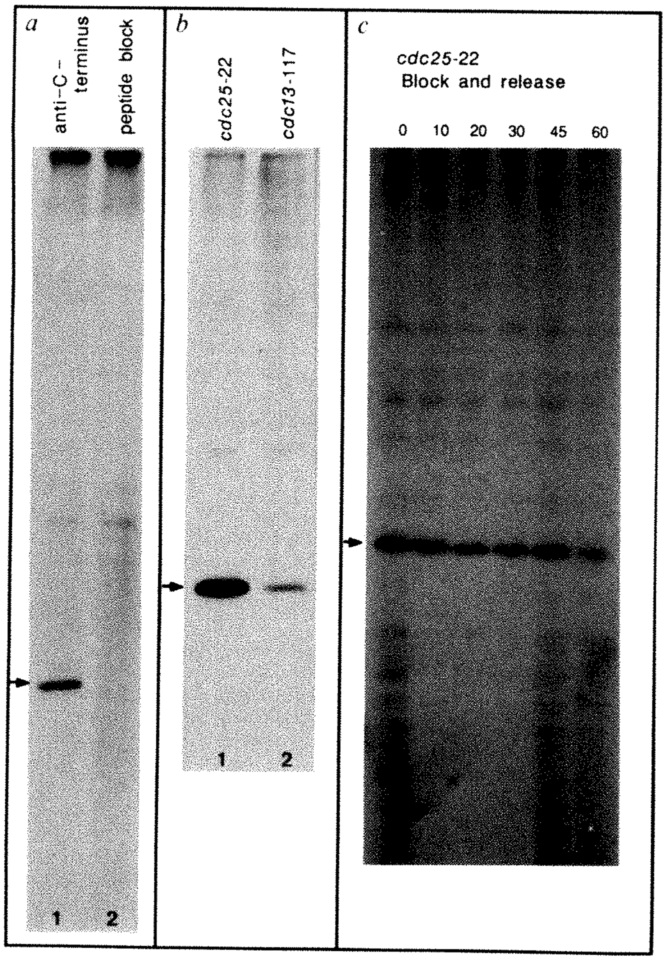


FIG. 1 Phosphorylation of pp34 during the G2-M phase transition. *a*, Wild-type *S. pombe* strain 972 was labelled with [^{32}P]orthophosphate and lysed as described[44]. The pp34 protein was immunoprecipitated with excess antibody raised against the C-terminal seven amino acids of pp34 (ref. 29) (lane 1) or with the same antibody pre-incubated with 100 ng of the C-terminal peptide (lane 2). *b*, Immunoprecipitates of pp34 from equivalent amounts of ^{32}P-labelled *cdc25*-22 (lane 1) or *cdc13*-117 (lane 2) cells arrested at 36 °C. *c*, Immunoprecipitates of pp34 from equal numbers of *cdc25*-22 cells labelled with [^{32}P]orthophosphate for 4.5 h at 36 °C and shifted to 25 °C for 0, 10, 20, 30, 45 and 60 min. Arrows indicate the position of pp34.

METHODS. *S. pombe cells* (5 or 10 ml) at 2-4 $\times 10^6$ cells per ml were labelled with 1-3 mCi [^{32}P]orthophosphate in reduced phosphate minimal medium as described earlier[29,44]. Wild-type strain 972 was labelled at 30 °C for 4 h and *cdc25*-22 and *cdc13*-117 strains at 36 °C for 4 or 4.5 h. Exponentially growing unlabelled wild-type cells (10^8) were added and lysis was performed as reported[29] with modifications[44]. The pp34 protein was visualized by autoradiography after separation on SDS-17.5% polyacrylamide gels. Exposure was for 3-16 h at −70 °C with intensifying screens. Gel bands were quantitated by scintillation counting.

Tyrosine phosphorylation site

As a first step towards identifying the site(s) of tyrosine phosphorylation, we examined the phosphopeptide composition of pp34. The patterns of pp34 tryptic phosphopeptides were qualitatively identical when derived from exponentially growing wild-type *S. pombe* cells (Fig. 4*a*) or from cells arrested in late G2 (Fig. 4*b*). The pp34 protein contained one major phosphopeptide, termed phosphopeptide 1, and a cluster of minor peptides, collectively termed phosphopeptide 2 (Fig. 4*a, b*). Phosphopeptide 1 contained only phosphotyrosine (Fig. 4*c*) and was the only peptide to contain detectable levels of phosphotyrosine. Phosphopeptide 2 contained phosphothreonine (Fig. 4*d*). The low yield of the phosphothreonine-containing peptide relative to the phosphotyrosine-containing peptide is probably due to the relative insolubility of phosphopeptide 2 in our buffer system, a characteristic of large hydrophobic peptides. We were unable to detect a phosphoserine-containing tryptic phosphopeptide, presumably because of insufficient ^{32}P-labelled sample.

We were able to localize the tryptic peptide-containing phosphotyrosine to the N-terminal 3-4K fragment of the protein based on the following observations. First, *N*-chlorosuccinimide cleaves pp34 to generate a characteristic pattern of partial cleavage products ranging from ~18-32K (ref. 5). All of these fragments contain the N-terminus of the protein (ref. 5; unpublished observations). Because we found that all of the ^{32}P-labelled pp34 *N*-chlorosuccinimide fragments contained phosphotyrosine (data not shown), the tyrosine phosphorylation site had to lie within the 18K N-terminal fragment of the protein. Second, the largest fragment (~28K) derived from pp34 by partial *S. aureus* V8 protease digestion, fragment A (Fig. 4*e*), lacked phosphotyrosine (Fig. 4*g*). Because fragment A is generated by removal of a section of ~4K from the N-terminus of the protein (data not shown), the site of tyrosine phosphorylation was most probably in this ~4K N-terminal piece of pp34.

There are three tyrosine residues in this region of the protein which lie in two tryptic peptides[35]. One tryptic peptide (amino acids 1-6) contains Tyr 4 and the other (amino acids 10-20) contains both Tyr 15 and Tyr 19. The tryptic peptide containing Tyr 4 was unlikely to be phosphopeptide 1 for two reasons. First, its theoretical mobility in our two-dimensional peptide mapping system did not correspond to the migration of phosphopeptide 1. Second, phosphopeptide 1 comigrated in our two-dimensional separations with a phosphotyrosine-containing tryptic peptide derived from murine pp34, strongly suggesting that a peptide with the identical sequence is phosphorylated in murine pp34 (C. Norbury, K.L.G. and P.N., unpublished observations). Comparison of the murine[7] and *S. pombe* pp34 sequences[35] revealed that the only tryptic peptide in the relevant N-terminal region of pp34 present in both murine and *S. pombe* pp34 was the peptide containing Tyr 15 and Tyr 19.

To establish that phosphopeptide 1 contained amino acids 10-20, we synthesized this ^{32}P-labelled tryptic peptide *in vitro* and compared its migration in two-dimensional separations with that of phosphopeptide 1. To generate this ^{32}P-labelled tryptic peptide *in vitro*, a peptide corresponding to amino acids 7-26 of pp34 was synthesized (Fig. 5*a*), phosphorylated by immunoprecipitates of pp60$^{v\text{-}src}$ (Fig. 5*b*) on tyrosine (data not shown), and cleaved with trypsin. The resultant synthetic tryptic phosphopeptide (Fig. 5*c*, panel *A*) comigrated with phosphopeptide 1 (Fig. 5*c*, panel *C*). These data indicated that phosphopeptide 1 was a phosphotyrosine-containing peptide corresponding to amino acids 10-20.

From the migration of phosphopeptide 1 at different pHs, it appeared to contain only one phospate moiety (data not shown) indicating that Tyr 15 and Tyr 19 were not phosphorylated in the same peptide molecule. To rule out the possibility that phosphopeptide 1 consisted of a mixture of two phosphopeptides, one phosphorylated at Tyr 15 and the other at Tyr 19, phosphopeptide 1 was cleaved with thermolysin. As shown in Fig. 5*a*, there are two potential thermolytic cleavage sites between Tyr 15 and Tyr 19. If both tyrosine residues were phosphorylated, cleavage with thermolysin would generate at least two distinct phosphopeptides. However, as phosphopeptide 1 yielded only one phosphopeptide on thermolytic cleavage (Fig. 5*c*, panels *D* and *E*), then only one tyrosine residue could be the site of phosphorylation *in vivo*.

Tyrosine substitutions

The codons for Tyr 15 and Tyr 19 were changed independently by site-directed mutagenesis to encode the structurally similar amino acid phenylalanine. The wild-type and mutant proteins were expressed from multicopy plasmids in a strain in which the *cdc2* gene had been deleted. These cells were labelled with [^{32}P]orthophosphate and the phosphoamino-acid composition of the *cdc2* proteins was examined. Although the *cdc2*$^+$ and *cdc2.Phe19* proteins contained all three phosphoamino acids (Fig. 6*a*, panels *A* and *C*), phosphotyrosine was absent in the *cdc2.Phe15* protein (Fig. 6*a*, panel *B*). This result confirmed that Tyr 15 was the site of phosphorylation.

The phenotypes of cells deleted for *cdc2*$^+$ and expressing plasmid-borne *cdc2*$^+$ or *cdc2.Phe19* were indistinguishable from that of wild-type cells (Fig. 6*b*, panels *A* and *B*). In contrast, cells expressing *cdc2.Phe15* grew very slowly and had the general appearance of '*wee*' mutants[36,37], septating at an average length of 7 μm rather than at the wild-type size of 14 μm (Fig. 6*b*, panels *C*-*F*). An abnormally high percentage of the cells contained septa (some very wide) and a large proportion of the cells were either anucleate, binucleate, had nuclei that were cut by septa, or had fragmented nuclei (Fig. 6*b*, panels *C*-*F*). These pleiotropic and deleterious effects of the *cdc2.Phe15* mutant are not observed in other single *wee* mutants such as *wee1*-50, *cdc2*-1w, or *cdc2*-3w (refs 36, 37). However, they are similar to the effects generated by the double mutant, *wee1*-50 *cdc2*-3w (ref. 24). This strain undergoes mitotic catastrophe at the *wee1*-50 restrictive temperature; the cells enter mitosis so early that

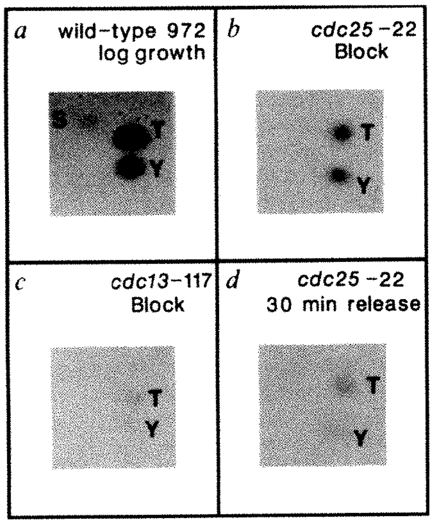

FIG. 2 Phosphoamino-acid compositions of pp34: *a*, pp34 from exponentially growing wild-type cells; *b*, pp34 from *cdc25*-22 cells labelled at 36 °C for 4.5 h; *c*, pp34 from *cdc25*-22 cells labelled at 36 °C and shifted to 25 °C for 30 min; *d*, pp34 from *cdc13*-117 cells labelled at 36 °C. Key: S, phosphoserine; T, phosphothreonine; Y, phosphotyrosine.

METHODS. ^{32}P-labelled pp34 immunoprecipitates were obtained as described in the legend to Fig. 1, subjected to partial acid hydrolysis, and the phosphoamino acids were resolved by two-dimensional thin-layer electrophoresis as described[45,46]. The sample of wild-type pp34 was derived from twice the number of cells labelled with more [^{32}P]orthophosphate. Samples containing 50-350 c.p.m. were loaded onto thin-layer cellulose and exposed for 6 days at −70 °C with intensifying screens. Thin-layer electrophoresis was performed on a CBS Scientific apparatus.

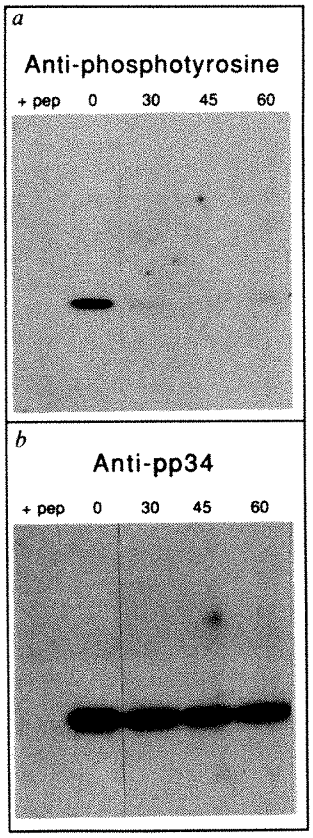

FIG. 3 Western blots of pp34 immunoprecipitates. Exponentially growing *cdc25*-22 cells at 3×10^6 cells per ml were arrested at 36 °C for 4.5 h. At each time interval (0, 30, 45 and 60 min) after shift to 25 °C, 10^8 cells were lysed and subjected to immunoprecipitation with the anti-C-terminal peptide serum or at time 0 with the anti-C-terminal peptide serum pre-incubated with excess peptide as described in the legend to Fig. 1. Each immunoprecipitate was divided in half, and each half was resolved separately on SDS-17.5% polyacrylamide gels, blotted onto Immobilon-P, and probed with either anti-phosphotyrosine antibodies (*a*) or anti-pp34 antibodies (*b*), followed by ^{125}I-labelled protein A. The main band corresponds to pp34.

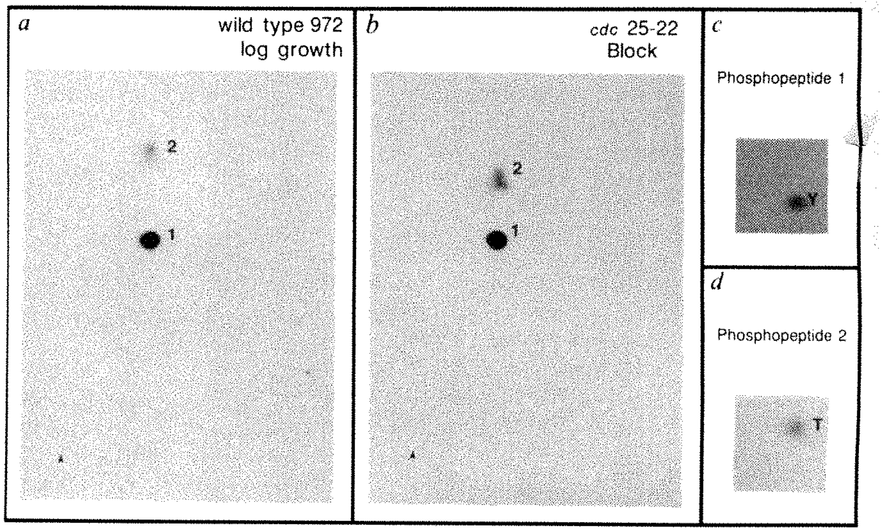
METHODS. The 3.4-kilobase *Pst*I genomic fragment of *cdc2*$^+$ was cloned into the vector pTZ19R (Pharmacia). The four introns in *cdc2*$^+$ were removed and a *Nde*I site was created at the initiating methionine by site-directed mutagenesis as described[5,47]. A *Bam*HI site was introduced 36 base pairs downstream of the stop codon by changing the sequence CTATCC to GGATCC by site-directed mutagenesis. All site-directed mutagenesis was carried out with an Amersham *in vitro* mutagenesis kit according to the manufacturer's instructions. The *Nde*I-*Bam*HI *cdc2*$^+$ fragment was subcloned into the bacterial expression vector pRK171 and expressed in the bacterial strain BL21(DE3) as reported previously[5,31]. After lysis of the bacteria with a French press, *cdc2* protein was purified from insoluble inclusion bodies by solubilization in gel sample buffer and electroelution from SDS-polyacylamide gels. Polyclonal rabbit serum was raised in rabbits by injection of 500 μg of pp34 near the popliteal lymph node first in complete Freund's adjuvant and thereafter every four weeks with the same amount of protein mixed with incomplete Freund's adjuvant. One antiserum (4711) was used at a 1:500 dilution for western blotting. Western blotting with anti-pp34 antibodies and anti-phosphotyrosine antibodies (from M. Kamps and B. Sefton) was performed as described[48], except that 10 μCi of ^{125}I-labelled protein A at 2-10 μCi per μg protein A was used to detect rabbit immunoglobulins. Exposures were for 10 days for *a* and 3 days for *b* at −70 °C with intensifying screens.



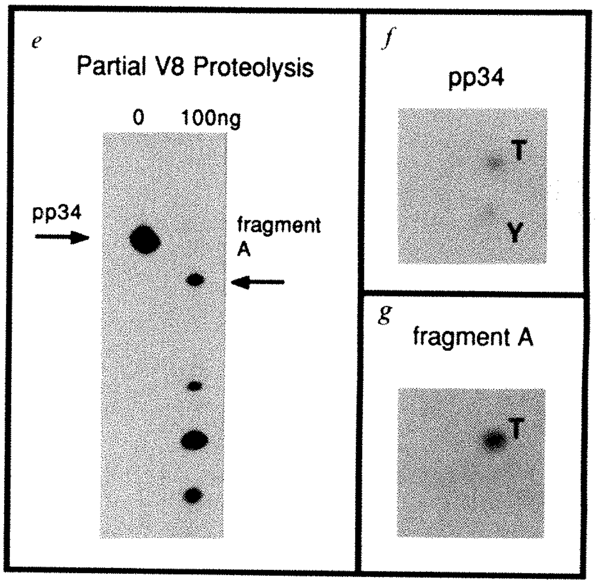


FIG. 4 Tryptic peptide and partial *S. aureus* V8 peptide analysis of pp34. *a*, Tryptic phosphopeptides of pp34 from ^{32}P-labelled exponentially growing 972 cells. *b*, Tryptic phosphopeptides of pp34 from ^{32}P-labelled *cdc25-22* cells arrested at 36 °C. Electrophoresis was at pH 4.72 in the horizontal dimension, with the anode on the left. The origins are indicated with arrowheads. *c*, Phosphoamino-acid analysis of phosphopeptide 1. *d*, Phosphoamino-acid analysis of phosphopeptide 2. *e*, One-dimensional peptide map of pp34 from *cdc25-22* cells arrested at 36 °C treated with 0 or 100 ng *S. aureus* V8 protease. *f*, Phosphoamino-acid analysis of undigested pp34. *g*, Phosphoamino-acid analysis of pp34 V8 fragment A.

METHODS. ^{32}P-labelled pp34 immunoprecipitates were subjected to tryptic digestion, and the tryptic phosphopeptides were separated in two dimensions as detailed previously[46,49]. Phosphoamino-acid analysis was as described in the legend to Fig. 2. One-dimensional peptide maps of pp34 were prepared on SDS-20% polyacrylamide gels with 0 or 100 ng of *S. aureus* V8 protease (Boehringer) as described[49]. Fragment A yielded the same number of *N*-chlorosuccinimide products as intact pp34 and reacted with PN24, but not an antipeptide serum directed against the N-terminal seven amino acids of the protein[29] (data not shown). This demonstrated that fragment A was generated by cleavage of an N-terminal peptide from the protein. Exposure times were 4–6 days at −70 °C with intensifying screens. Cerenkov c.p.m. loaded onto thin-layer plates ranged from 50–350 c.p.m.

cell death frequently results. Like this double mutant, *cdc2.Phe15* appears to be independent of some inhibitory signal(s) which normally delays entry into mitosis until all other necessary steps in the cell cycle have been completed. The very slow growth of the *cdc2.Phe15* strain can be accounted for by the large percentage of inviable cells which are produced in each generation from lethal premature entry into mitosis. When *cdc2.Phe15* was expressed in *cdc2*$^+$ strains, the same phenotype was observed (Fig. 6*b*, panels *G* and *H*), demonstrating that the mutant is dominant over wild-type *cdc2*$^+$ when present on a multicopy plasmid. Also, *cdc2.Phe15* is able to rescue the temperature-sensitive mutant *cdc2*-33, providing further evidence that it encodes a functional *cdc2* protein. In addition, like the *wee* mutant *cdc2*-3w, it is able to rescue the conditionally lethal *cdc25-22* strain.

Discussion

We have shown in this paper that *S. pombe* pp34 is multiply phosphorylated in exponentially growing cells. It is maximally phosphorylated in late G2 and as cells enter mitosis, the level of pp34 phosphorylation decreases. The protein kinase activity of pp34 in *S. pombe* was shown in earlier reports[12,17] to increase from a low level in late G2 (at a *cdc25*-22 block point) to its maximum level in mitosis (during a *cdc25*-22 release) with the same kinetics as described here for dephosphorylation. A decrease in pp34 phosphorylation as cells enter mitosis has been observed previously in starfish[11], frog[25,26], and mammalian[27,28] cells. Because dephosphorylation in these higher eukaryotes is coincident with an increase in pp34 protein kinase activity towards histone H1, it has been proposed that dephosphorylation might regulate the activation of pp34 (refs 11, 25, 26, 28). The fact that pp34 enzymatic activity is inversely correlated with its level of phosphorylation during the G2-M transition in *S. pombe* and in several higher eukaryotes indicates that this potential regulatory mechanism has been highly conserved throughout eukaryotic evolution.

A previous investigation in our laboratory did not detect any changes in pp34 phosphorylation levels as *S. pombe* cells moved through the cell cycle[29]. The most likely explanation for the apparent discrepancy between our two reports lies in the methods used for obtaining synchronous cell cultures. In the present study, we used the temperature-sensitive mutations *cdc25*-22 and *cdc13*-117, which arrest either in late G2 or mitosis, respectively. On shift from the restrictive to the permissive temperature, *cdc25*-22 cells enter mitosis in a highly synchronous fashion. In the earlier study, cells were fractionated by size using an elutriation rotor[29]. Although this method causes the least physiological disturbance to the cells, it does not achieve such good cell-cycle synchrony. If pp34 dephosphorylation in *S. pombe* is quite transient and cells arrived at a point in mitosis when dephosphorylation occurs somewhat asynchronously in our experiments, we would only expect to see a small overall change. Because we observed only a fourfold dephosphorylation of pp34 in cultures synchronized by a *cdc25*-22 block and release, it is likely that dephosphorylation would have been extremely difficult to detect in cultures synchronized by elutriation. A small change in overall pp34 phosphorylation might also indicate that only a subpopulation of pp34 molecules in *S. pombe* is subject to dephosphorylation during the G2-M transition. Like the previous study on pp34 phosphorylation in *S. pombe*[29], phosphorylation changes were not detected in the *S. cerevisiae* homologue of pp34 during the cell cycle[30]. More recently, however, a transient phosphorylation of the *CDC28* gene product on tyrosine residues has been observed (S. Reed, personal communication).

We have found both by phosphoamino-acid analysis and by immunoblotting with anti-phosphotyrosine antibodies that pp34 contains phosphotyrosine. The phosphotyrosine content of pp34 is maximal in late G2 and decreases with the same kinetics as total ^{32}P content of the protein when cells enter mitosis. Phosphotyrosine was not detected in a previous study of pp34 phosphorylation, although phosphothreonine and phosphoserine were detected in roughly the same proportion that we have observed[31]. We do not know the reason for this discrepancy but suspect that it is due to the very different labelling conditions and cell densities used.

The *cdc2*$^+$ protein kinase is the first yeast protein known to contain phosphotyrosine. There has been a report of an unknown protein reacting with anti-phosphotyrosine antibodies in yeast lysates but this has not been substantiated by phosphoamino-acid analysis[38]. Because anti-phosphotyrosine antibodies have been reported to react in some circumstances with phosphohistidine, phosphothreonine and phosphoserine residues within proteins (ref. 39; R. Lindberg and T. Hunter, personal communication), reports relying solely on reactivity with anti-phosphotyrosine antibodies have been regarded with some scepticism. Very small amounts of phosphotyrosine have been obtained from partial acid hydrolysates of total cell protein[33]. However, other modifications of tyrosine such as adenylylation can yield phosphotyrosine upon partial acid hydrolysis[40]. Thus, whether the tiny amounts of phosphotyrosine detected in acid hydrolysates are actually due to modification of tyrosine residues by enzymatic phosphorylation remains an open issue. Tyrosine-protein kinase activity in yeast, on the other hand, has been demonstrated more definitively. A very low level of activity that phosphorylates a copolymer of glutamic acid and tyrosine on tyrosine has been identified in crude lysates of *S. cerevisiae*[34]. In multicellular eukaryotes, tyrosine phosphorylation has been more readily detected and is intrinsic to more than 30 proteins[41]. Of the diverse array of protein-tyrosine kinases known, most appear to be associated with the plasma membrane, either as growth factor receptors or as putative transducers of extracellular stimuli[41]. Because such a highly elaborate system for responding to growth factors and other intercellular signals is unlikely to be required in a unicellular organism, it is probable that many fewer protein-tyrosine kinases exist in yeast. However,

FIG. 5 Localization of the tyrosine phosphorylation site in pp34. *a*, Sequence of the synthetic peptide corresponding to amino acids 7–26 of pp34. Arrows indicate cleavage sites for trypsin and thermolysin. The two tyrosines are boxed. *b*, Phosphorylation of the synthetic peptide by pp60$^{v\text{-}src}$ in the presence of [γ-^{32}P]ATP. The plus and minus signs refer to reactions which did or did not contain the peptide, respectively. The arrow indicates the position of phosphorylated peptide. *c*, The synthetic peptide phosphorylated by pp60$^{v\text{-}src}$ was cleaved with trypsin and resolved in two dimensions (panel *A*). The tryptic phosphopeptide containing phosphotyrosine shown in Fig. 4, *a* and *b*, was re-run separately (panel *B*). Equal Cerenkov c.p.m. of each tryptic phosphopeptide shown separately in panels *A* and *B* were mixed in panel *C*. The tryptic phosphopeptide shown in *B* was cleaved with thermolysin and resolved in two dimensions (panel *D*). Equal Cerenkov c.p.m. of each phosphopeptide run separately in panels *B* and *D* were mixed in panel *E*. Cerenkov c.p.m. loaded onto cellulose plates ranged from 60–100 c.p.m. Exposure times were 5 days at −70 °C with intensifying screens. Electrophoresis was at pH 1.9 in the horizontal dimension with the anode on the left.

METHODS. A peptide corresponding to amino acids 7–26 of pp34 was synthesized using a Applied Biosystems 430A synthesizer and purified by reverse-phase HPLC. Amino-acid analysis confirmed the authenticity of the sequence. Immunoprecipitation of pp60$^{v\text{-}src}$ was from LA29-transformed rat-1 cells with monoclonal antibody 327 (ref. 50; provided by T. Hunter) as described previously[49]. Immunoprecipitates of pp60$^{v\text{-}src}$ were resuspended in 30 μl 20 mM Tris-HCl, pH 7.5, 10 mM $MnCl_2$ and 3 μl 100 mM Tris-HCl, pH 7.5, with or without 3 μg of the synthetic peptide. Reactions were initiated by the addition of 30 μCi [γ-^{32}P]ATP and allowed to proceed at room temperature for 15 min. Immune complexes were pelleted by brief centrifugation and 10 μl of the supernatants were added to 10 μl of 2 × sample buffer. After heating to 100 °C for 2 min, this 20-μl portion was resolved on an SDS-25% polyacrylamide gel and the phosphorylated peptide was visualized by autoradiography. The remainder of the synthetic peptide phosphorylated by pp60$^{v\text{-}src}$ was purified by cellulose thin-layer electrophoresis at pH 1.9. It was eluted from the cellulose with pH 1.9 buffer, lyophilized, resuspended in 20 μl 50 mM ammonium bicarbonate, pH 8.0, and digested with 2 μg trypsin for 2 h at 37 °C. Phosphopeptide 1 (Fig. 4*a*, *b*) was eluted from cellulose plates and digested with thermolysin as described above, except that cleavage was performed at 55 °C. All other manipulations of phosphopeptides, including two-dimensional separation, were carried out as described previously[46,49].

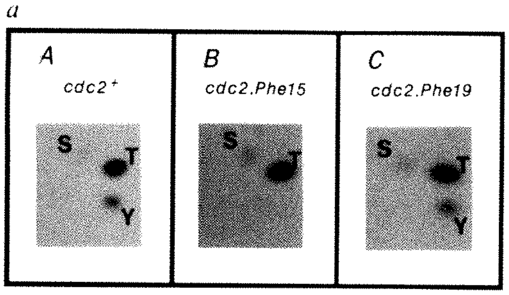
the protein-tyrosine kinases that are present in yeast might have fundamental roles in the assessment of growth and/or nutritional status and relate that information to progress through the mitotic cell cycle.

There is a single detectable site of tyrosine phosphorylation in fission yeast pp34 and we have identified it as Tyr 15. This residue lies directly within a part of the postulated nucleotide binding domain of pp34, the GXGXXG motif[42]. The location of Tyr 15 leads us to suggest that the function of tyrosine phosphorylation in pp34 is to prevent ATP binding either sterically and/or by electrostatic repulsion, thereby inactivating the protein. This hypothesis is consistent with the observation that dephosphorylation of pp34 correlates with increased protein kinase activity. Modulation of nucleotide-binding ability by phosphorylation would represent a novel mechanism of protein kinase regulation. A comparison of protein kinase sequences[42] reveals that *cdc2*$^+$ and its functional homologues are not unique in containing a tyrosine at this position. It is possible, therefore, that other protein-serine/threonine and protein-tyrosine kinases might be regulated by tyrosine phosphorylation within their ATP-binding domains.

The potential role of tyrosine phosphorylation in the regulation of pp34 was addressed by changing the codon specifying Tyr 15 to that encoding phenylalanine and then examining the effect of this mutation in *S. pombe*. Based on the observation that *cdc2.Phe15* was able to rescue a temperature-sensitive allele of *cdc2*, as well as a strain in which the *cdc2*$^+$ gene had been disrupted (although the growth rate of the rescued strains was low), we conclude that the mutant *cdc2.Phe15* protein retains enzymatic activity. Cells expressing *cdc2.Phe15* either with or without *cdc2*$^+$ entered mitosis at a small cell size and exhibited a wide range of abnormal phenotypes suggestive of mitotic catastrophe. Many were anucleate, binucleate, had septation defects, or had fragmented nuclei. Cell division in this strain resulted in many inviable progeny, accounting for its slow doubling time. The ability of this strain to grow at all indicates that this single mutant is not quite as detrimental as the double mutant *wee1*-50 *cdc2*-3w. As mentioned earlier, the combination of *wee1*-50 and *cdc2*-3w alleles results in mitotic catastrophe preventing formation of colonies at the *wee1*-50 nonpermissive temperature[24]. Thus, although *cdc2.Phe15* appears to bypass much of the normal inhibition acting to time entry into mitosis properly, this mutant does not appear to be de-regulated completely.

The *cdc2.Phe15* mutant protein is still phosphorylated on threonine and serine residues. We have shown in this report that phosphothreonine as well as phosphotyrosine decreases as cells enter mitosis, suggesting that phosphothreonine might also be involved in the regulation of pp34 activity. It will be interesting to identify the sites of threonine and serine phosphorylation and assess the role of these phosphorylation events in the regulation of pp34.

Because pp34 is regulated by tyrosine phosphorylation and dephosphorylation, presumably at least one protein-tyrosine kinase and phosphatase contribute to regulation of the *S. pombe* mitotic cell cycle. The *cdc25* gene function, which normally is required for activation of pp34, is bypassed by *cdc2.Phe15* because *cdc2.Phe15* can rescue a temperature-sensitive mutation of this gene. Although the function of *cdc25* is unknown and its amino-acid sequence does not reveal similarities to the sequence of any published protein phosphatase or protein kinase inhibitor[18], these findings would be consistent with a role for *cdc25* in the activation of a protein-tyrosine phosphatase or the inhibition of a protein-tyrosine kinase.



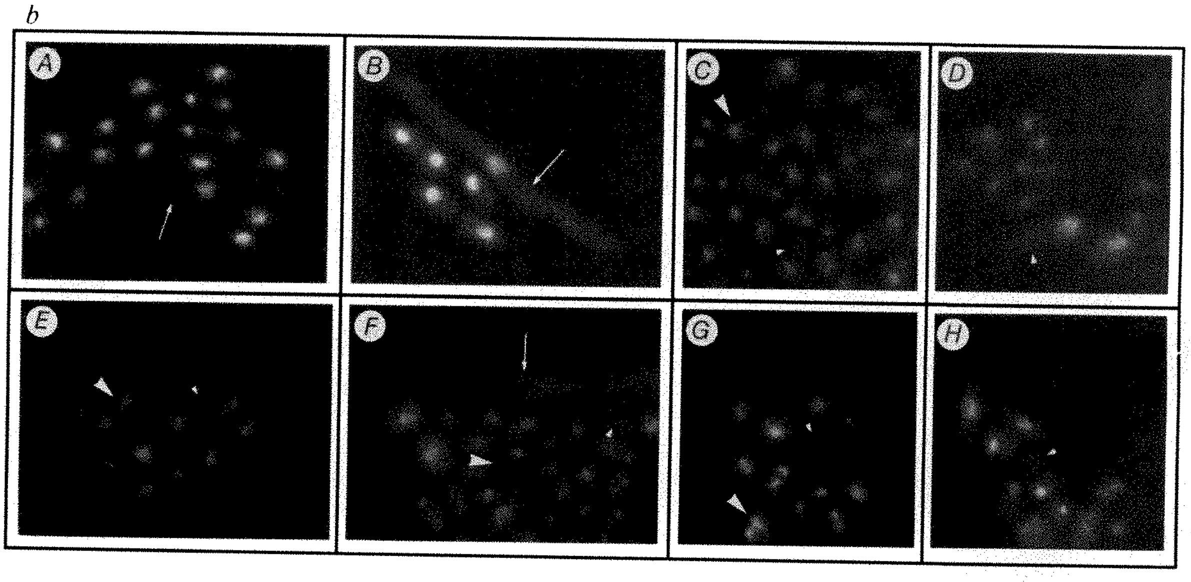


FIG. 6 Phenotype of *cdc2* mutants. *a*, Phosphoamino-acid analyses of pp34 proteins from *S. pombe* cells with a deleted *cdc2*$^+$ gene complemented by plasmid-borne *cdc2*$^+$, *cdc2.Phe15*, or *cdc2.Phe19* labelled with [^{32}P]-orthophosphate. *b*, DAPI staining. *S. pombe* cells with a deleted *cdc2*$^+$ gene complemented by plasmid-borne (*A*) *cdc2*$^+$, (*B*) *cdc2.Phe19*, or (*C, D, E* and *F*) *cdc2.Phe15*. *S. pombe leu1*-32 cells complemented by a plasmid containing *LEU2* and *cdc2.Phe15* (*G* and *H*). Long arrows indicate cells which have lost *cdc2*-containing plasmids and are *cdc*$^-$. Arrowheads point to cells undergoing abnormal septation and anucleate cells.

METHODS. Mutagenesis of Tyr 15 and Tyr 19 in *cdc2*$^+$ was carried out as described in the legend to Fig. 3 with 20-base-long mutagenic oligonucleotides. The mutant genes were transformed into the diploid strain, h^+/h^{90}, *leu1*-32/*leu1*-32, *ura 4*-D18/*ura 4*-D18, *cdc2*$^+$/*cdc2::ura4*$^+$, *ade6*-704/*ade6*-704, on a multicopy plasmid containing *LEU2* (ref. 44). *Leu*$^+$ transformants were allowed to sporulate and unsporulated cells were digested with helicase as described[44]. Spores were plated onto minimal plates lacking leucine and uracil. Colonies obtained from this selection were transferred to complete YEA medium[44]. The same vector was also used to transform *leu1*-32 cells with *cdc2.Phe15*, and *leu*$^+$ transformants were selected. ^{32}P-labelling, immunoprecipitation and phosphoamino-acid analysis were performed as described in the legends to Figs 1 and 2. DAPI staining was performed as reported elsewhere[44].

The tyrosine residue that is phosphorylated in pp34 is conserved among all known pp34 homologues from yeast to humans[6-8,32,35] and it is now known that pp34 contains phosphotyrosine in human[43], mouse[28], frog[25], *S. pombe* (this report) and *S. cerevisiae* (S. Reed, personal communication) cells. It is possible, therefore, that the tyrosine residue phosphorylated in *S. pombe* pp34 is also phosphorylated in pp34 from other species and that control of pp34 activity by dephosphorylation of this residue might be conserved throughout evolution. Purified mammalian pp34 can be phosphorylated on tyrosine by $pp60^{v\text{-}src}$ *in vitro*[43], as can a synthetic peptide corresponding to amino acids 7-26 of *S. pombe* pp34. However, it should be kept in mind that $pp60^{v\text{-}src}$ is capable of phosphorylating nonphysiologically relevant protein substrates *in vitro*[41] and that there is no evidence as yet that $pp60^{c\text{-}src}$ directly phosphorylates pp34 *in vivo* in any system. The identification and characterization of the putative protein-tyrosine kinase and phosphotyrosine phosphatase responsible for regulating pp34 phosphotyrosine levels in *S. pombe* should enhance our understanding of cell-cycle control in all eukaryotes. □

The *Caenorhabditis elegans* gene *unc-22* encodes a very large muscle protein, called twitchin, which consists of a protein kinase domain and several copies of two short motifs. The sequence of twitchin has unexpected similarities to the sequences of proteins of the immunoglobulin superfamily, cell adhesion molecules and vertebrate muscle proteins, including myosin light-chain kinase. These homologies, together with results from earlier genetic and molecular analyses, indicate that twitchin is involved in a novel mechanism of myosin regulation.

THE gene *unc-22* is one of more than 40 genes important for muscle assembly and function that have been identified in the nematode *Caenorhabditis elegans*[1]. Mutant animals that lack the *unc-22*-encoded protein (Unc-22) have a unique and puzzling phenotype: a nearly constant twitching of the body muscles. These muscles are unable to develop or sustain normal contractions. Instead, small regions within the myofilament lattice of individual muscle cells contract transiently in the absence of contraction of the adjacent lattice. Mutations are readily recovered and most of these are conditionally dominant[2,3]. All available extragenic suppressors of *unc-22* mutants are missense mutations of the main body wall myosin heavy-chain gene *unc-54*[4,5], indicating that the Unc-22 protein may act through myosin to regulate contraction. The *unc-22* gene has been cloned by transposon tagging[6] and this has permitted a molecular analysis of the gene[7].

The protein product of *unc-22*, which we call twitchin after the distinctive mutant phenotype, is located in the myosin-containing regions of muscle cells and has a relative molecular

mass of ~600,000 (M_r 600 K)[7]. Several very large proteins of unknown function, such as titin[8-13], nebulin[14] and dystrophin[15], have been found in vertebrate muscle, but their relationships to twitchin are unclear. To understand the possible role of twitchin in muscle and to facilitate the search for homologous genes in other organisms, we determined the sequence of the *unc-22* gene.

The protein encoded by *unc-22*

The *unc-22* gene had been estimated to span more than 30 kilobases (kb), as deduced from DNA insertions and deletions that affect *unc-22* activity[7] (Fig. 1*a*). We sequenced a cosmid[16] and two adjacent restriction fragments to cover the entire region (Fig. 1*b*). The cosmid was sequenced by using a shotgun library prepared from total cosmid DNA, and the restriction fragment sequences were determined by conventional means. The resulting 47,081 base pairs (bp) of continuous sequence (GenBank EMBL accession number X15423) included the sites[17] of the two most extreme rearrangements (*st139* and *st185*; Fig. 1*a*), with 32,160 bp separating them.

The *unc-22* coding sequence in this genomic sequence was identified by using codon bias[18] and the consensus donor and acceptor sites of *C. elegans* introns[19]. The repeated nature of the encoded protein sequence (see below) also aided in the exon-intron assignments. Furthermore, complementary DNA sequence (Fig. 1*b*) confirmed the four 3'-most exons and also identified the poly(A) site (at position 34,386).

The coding sequence is divided among 14 exons, the largest of which is 9,613 bp. The 13 introns have the base composition and size typical of *C. elegans* introns[19]. The ATG at position 14,070 has tentatively been assigned as the initiator methionine

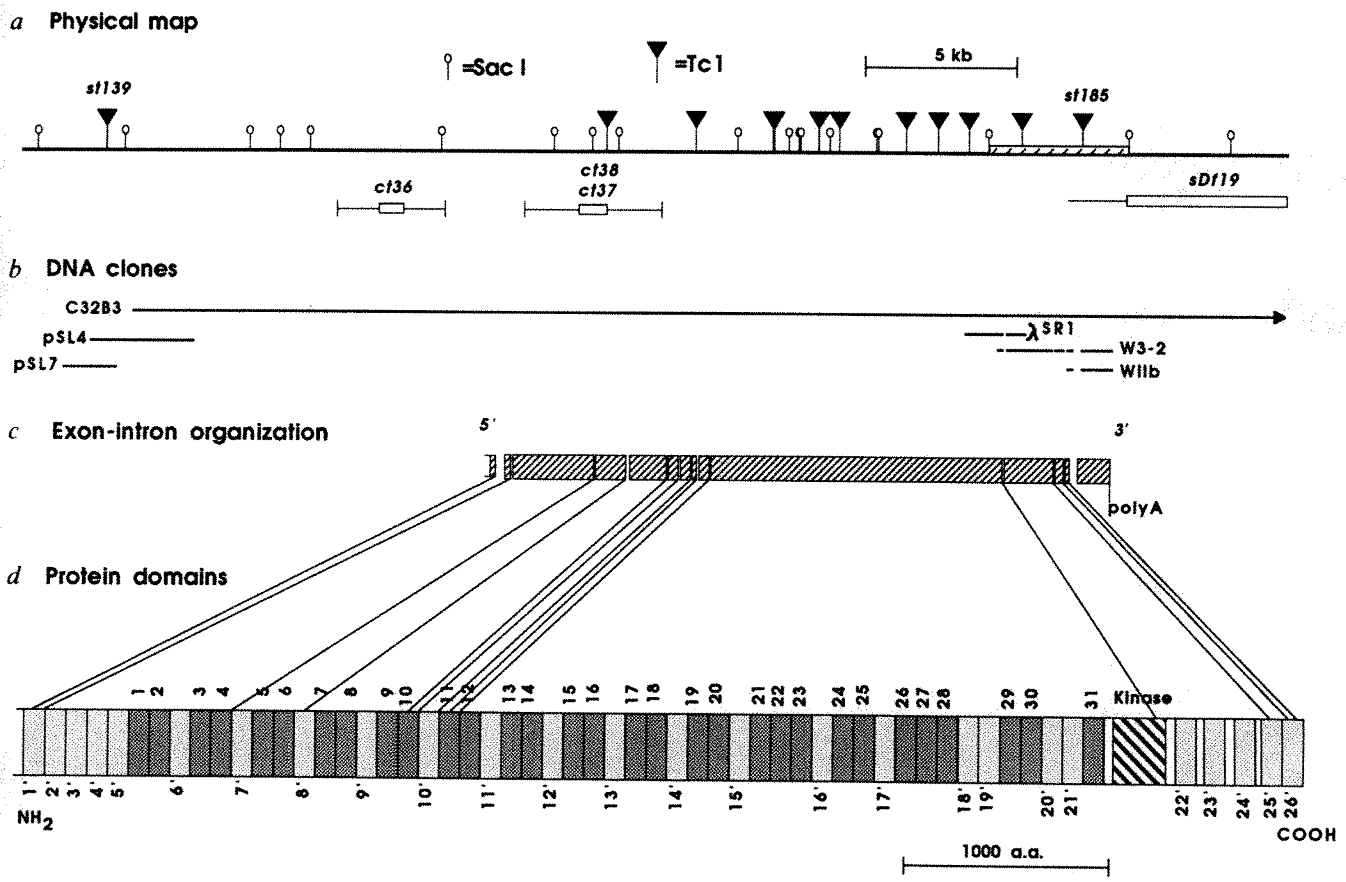

FIG. 1 The *unc-22* gene and its encoded polypeptide. *a*, Physical map of the *unc-22* region. The restriction map, the position of 12 transposon Tc*1* insertions that result in the *unc-22*-mutant phenotype, and the positions of the deficiencies *sDf19, ct36, ct37* and *ct38* are shown (modified from ref. 7). The position of the breakpoint of the deficiency *sDf19* orientates the physical map relative to the genetic map[6,36-38]. The open boxes represent the extent of deletions and the lines extending from them indicate uncertainties of position. The stippled box to the right indicates the 4.6-kb fragment used to probe the cDNA libraries. *b*, DNA clones that were sequenced. A portion of the cosmid clone C32B3, and two small overlapping plasmid genomic clones pSL4 and pSL7 are shown. LSR1, W3-2 and W11b on the right are cDNA clones. *c*, Exon-intron organization of the *unc-22* gene. The uncertaintiy in the 5' end of the transcript is denoted by the open box at the left. The polyadenylation addition site is indicated at the right. The scale is the same as in *a* and *b* and the gene is aligned with the physical map in *a*. *d*, Schematic representation of domains in the twitchin amino-acid sequence. The single protein kinase domain is denoted by the hatched box, the 31 copies of motif I are represented as darkly shaded boxes (1-31), and the 26 copies of motif II are represented as lightly shaded boxes (1'-26'). Small regions lacking homology either to themselves or to motifs I or II are indicated by the unshaded areas. Uncertainty in the translation start site is indicated by the open box at the left.

METHODS. A single shotgun M13 library was constructed[39] from the entire cosmid C32B3 (ref. 16). Dideoxy sequencing[40,41] reaction products from all clones were fractionated on polyacrylamide wedge-spacer gradient gels[42] and from one-third of the clones, on non-gradient gels for extended readings. Sequences were compiled and analysed with the programs of R. Staden[43]. After analysis of ~600 independent clones with ~1,050 gel readings, the sequence lay in 20 contigs. To close these gaps, thirty oligonucleotide primers (each 17-18 bases; synthesized by the Emory Microchemical Facility) were used to obtain a single contiguous sequence of 44,977 bp. To resolve ambiguities and read both strands of the cosmid insert we used 10 more oligonucleotide primers. The entire 47,081-bp sequence (including inserts of pSL4 and pSL7) was determined on both strands. Probable exons were determined by Staden's codon usage method, initially by using a codon table for abundantly expressed genes in *C. elegans*[18], and later using a codon table compiled from the *unc-22* gene itself. Candidate introns were detected by searching for consensus donor and acceptor sequences, and for conformity to the typical *C. elegans* intron[19]. The deduced amino-acid sequence was compared with others in the Protein Identification Resource database (release 20) and all possible reading frames of each GenBank DNA sequence (release 59) using the HOMOLOGY program of GENEPRO (Riverside Scientific Enterprises, Seattle, Washington).

codon. Although this is almost 13 kb from the *unc-22* (*st139*::Tc1) transposon insertion site (Fig. 1*c*), no likely exons could be found in the intervening region. The *st139* insertion could act at a distance or an unusually large intron could span the region. The TAA stop codon at 33,439 lies 66 bp downstream of the *st185* transposon insertion site and 948 bp upstream of the poly(A) site. We calculated the minimum message size to be 19,092 nucleotides, with a coding sequence of 18,147 bases. The predicted protein has 6,049 amino acids with an estimated M_r of 668,520.

Two ~100-amino-acid repeated motifs

Analysis of the predicted twitchin amino-acid sequence shows that most of the protein consists of two repeated motifs, each of ~100 amino acids (Fig. 1*d*). The most abundant motif, designated motif I, is present as 31 copies, arranged in 12 tandem pairs, 2 triplets and one singlet. The copies of motif I vary in length from 98–102 residues and are all rich in proline (~9%) (Fig. 2*a*). Comparison of all the copies against one another yields a consensus sequence in 55 of the positions scattered throughout the motif. Two regions particularly highly conserved between motif I copies are shown enclosed in boxes in Fig. 2*a*.

Each set of motif I copies is generally separated from the next set by a copy of a second motif, motif II, which varies in length from 91–95 residues. Motif II is repeated 26 times (Fig. 3*a*); the similarity of motif II copies to one another is less than that of motif I copies to one another, and less stringent criteria were used to derive a consensus sequence for motif II. One region of high conservation among motif II copies is boxed in Fig. 3*a*. Not all the copies of motif II are bracketed by motif I copies (Fig. 1*d*): five tandem copies of motif II occur in the N-terminal portion and five nearly tandem copies occur in the C-terminal portion of the polypeptide.

Five of the thirteen introns are positioned at the boundaries of motif I or motif II copies (introns 2, 3, 6, 7 and 9; see Fig. 1*c*). This is compatible with the notion that *unc-22* evolved by fusion of primordial genes containing either motif I or motif II, and then by duplication and divergence.

Similarity to myosin light-chain kinases

Searches of the PIR protein and GenBank DNA databases revealed that a C-terminal portion of twitchin devoid of motif I or II copies is homologous to the catalytic domains of protein kinases. The twitchin sequence has all 14 very highly conserved residues shared among all protein kinases[20]. The kinase portion of twitchin has greatest similarity to the kinase domain of the chicken smooth-muscle myosin light-chain kinase (csmMLCK)[21], no gaps are needed for the alignment of the two regions, with 52% identical residues over a stretch of 250 amino-acid residues (Fig. 4). The kinase portion of twitchin is also 44% identical (alignment without gaps) to the protein kinase domain of rabbit skeletal-muscle myosin light-chain kinase (rskMLCK; data not shown)[22]. Similar to csmMLCK and rskMLCK, twitchin has residues typical of serine/threonine kinases[20] (Fig. 4). Twitchin has no sequence homology to the calmodulin-binding domains of either csmMLCK (Fig. 4) or rskMLCK.

In addition to the homology between csmMLCK and twitchin in their kinase domains, we also found one copy of motif I and one-and-a-half copies of motif II in the published csmMLCK sequence (Figs 2*b*, 3*b* and 4). Both the order and spacing of motif I and motif II copies is conserved between the two sequences; recent cDNA-sequence data for csmMLCK indicates that

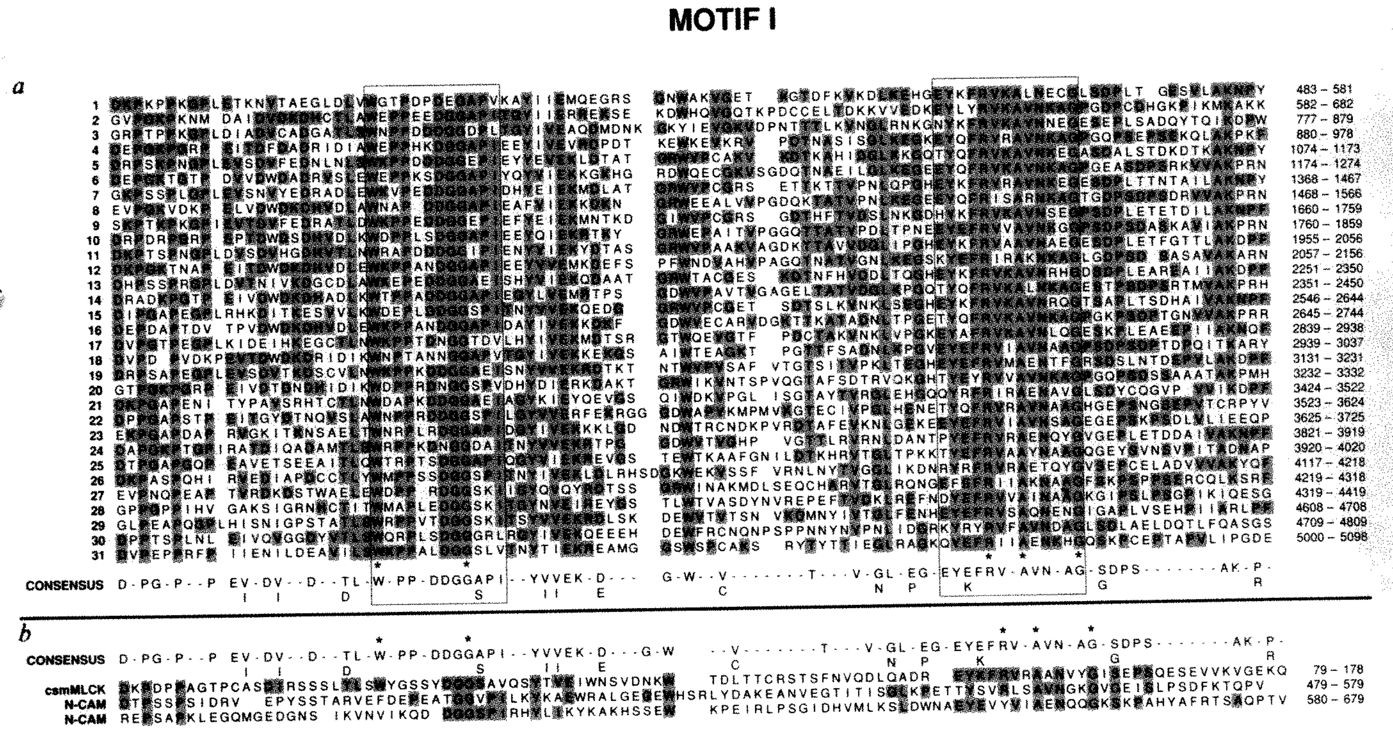

FIG. 2 Motif I (single-letter amino-acid code). *a*, The 31 copies of motif I. Numbers 1–31 on the left correspond to the darkly shaded boxes in Fig. 1*d*. The numbers on the right indicate positions in the twitchin deduced amino-acid sequence. Alignment was done by inspection. For each position, amino-acid residues found in at least 9 copies of motif I are shaded. The 55-residue consensus sequence is composed of residues that occur at corresponding positions in at least 14 out of 31 copies, or two residues that occur at corresponding positions between them in at least 19 out of 31 copies. Asterisks denote the five positions in which the same amino acid is found in all 31 copies. *b*, Similarity of motif I of twitchin to sequence in other proteins. The full copy of motif I in csmMLCK[21] is identical to the motif I consensus at 28 positions. For the two tandem copies of motif I in N-CAM[24], residues 479–578 are identical to the motif I consensus at 23 positions, and residues 580–673 are identical to the motif I consensus at 22 positions. Boxes enclose regions particularly conserved between motif-I copies.

the partial copy represents a complete copy of motif II and, indeed, yet another copy of motif II is upstream of that (N. Olson and A. R. Means, manuscript in preparation). By contrast, the rskMLCK lacks copies of either motifs I or II and its similarity to twitchin is limited to the protein kinase domain.

The high degree of similarity of twitchin with csmMLCK and rskMLCK in their kinase domains strongly indicates that one function of twitchin is to phosphorylate a muscle protein, presumably the regulatory myosin light chain. The extended similarity between twitchin and csmMLCK (37% identical and 47% similar allowing for conservative changes over a sequence of 644 residues in twitchin) indicates that these proteins possess additional conserved functions.

Motif II and immunoglobulin-like domains

The superfamily of proteins with sequence homology to immunoglobulins has been divided into three sets, the V set, the C1 set and the C2 set[23]. Motif II has homology to domains in the proteins of this superfamily, and greatest similarity to those in the proteins of the C2 set, a group that includes neural cell adhesion molecule (N-CAM), myelin associated glycoprotein (MAG), the receptor for platelet derived growth factor (PDGFR) and the Fc receptor (FcR) (Fig. 3*c*). The motif II consensus sequence matches 13 out of 25 residues in an immunoglobulin C2-set consensus sequence. The copies of twitchin motif II are more similar to one another than they are to other members of the immunoglobulin superfamily, presumably reflecting special functional constraints.

All previously recognized members of the immunoglobulin superfamily are cell surface or extracellular molecules, and yet twitchin (and csmMLCK) is totally intracellular. As might be expected for an intracellular molecule, the twitchin motif generally lacks the cysteines that form intra-chain disulphide bonds in immunoglobulin domains (copies 1′ and 20′ are the exception, in which both cysteines are found). The absence of these cysteines is not without precedent, because other members of the immunoglobulin superfamily have been found that lack the cysteines[23]. For these exceptions and in most copies of twitchin motif II, hydrophobic residues reside at the positions of the conserved cysteines.

Twitchin motifs and cell adhesion molecules

Motif I of twitchin is similar to two tandem segments in the neural cell adhesion molecule (N-CAM)[24] (residues 479-578 and residues 580-673), with many of the twitchin consensus residues present at a spacing similar to that in the N-CAM copies (Fig. 2*b*). These portions of NCAM have similarity to segments in other cell adhesion molecules of insects and mice[25,26]. This family of adhesion proteins has segments that are similar to the type III domains of fibronectin[25,27], as does twitchin motif I (especially over the last 33 residues of motif I). Twitchin, csmMLCK and these cell adhesion molecules contain both motifs I and II, but all other previously recognized members of the immunoglobulin superfamily have only motif II. It is striking that twitchin and the cell adhesion molecules N-CAM and fasciclin II each begin with five tandem copies of

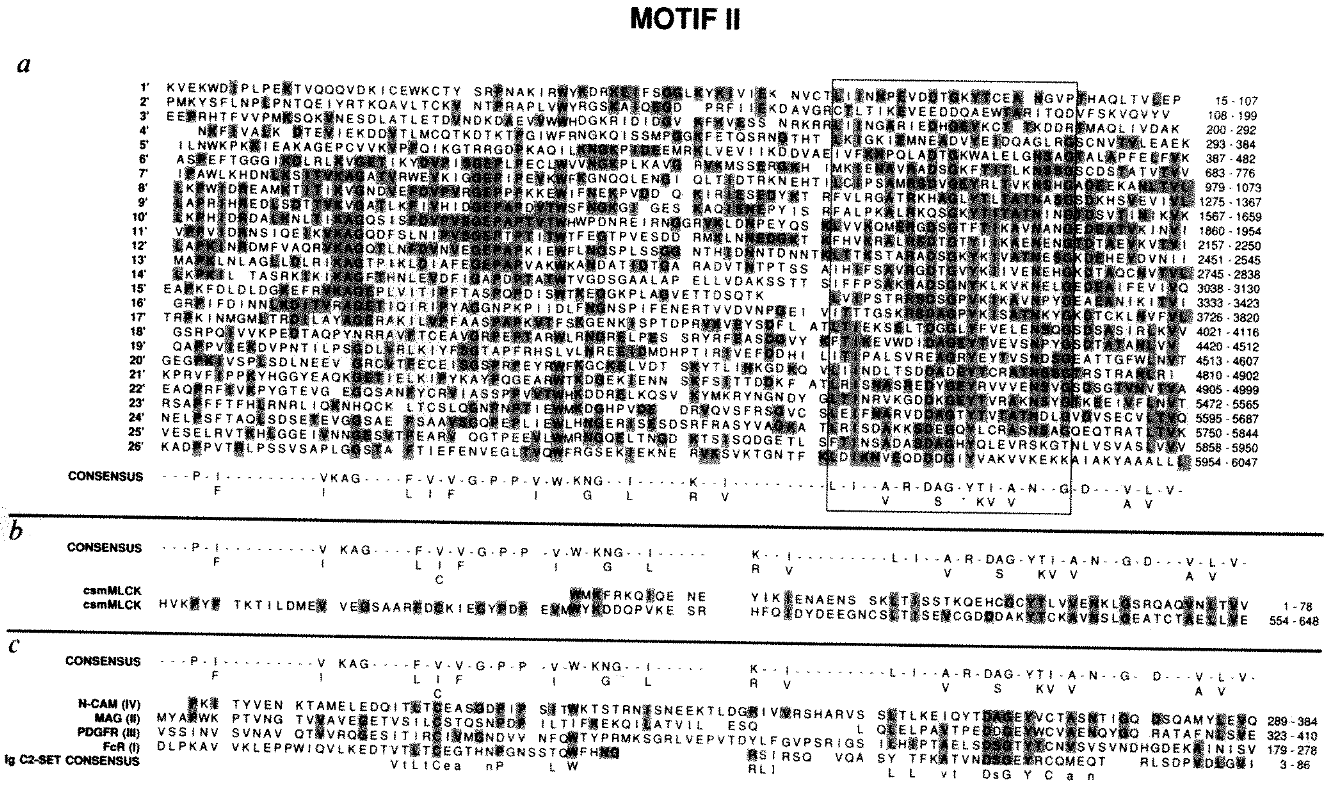

FIG. 3 Motif II (single-letter amino-acid code). *a*, The 26 copies of motif II in twitchin. Numbers 1′–26′ on the left correspond to the lightly shaded boxes in Fig. 1*d*. At each position, amino acids found in at least five copies are shaded. The consensus sequence was derived as residues present at corresponding positions in at least 9 out of 26 copies, or two residues that occur at corresponding positions between them at least 14 out of 26 copies. *b*, Similarity of motif II of twitchin to sequences in csmMLCK. Amino-acid residues identical to the consensus are shaded. The partial copy of motif II in csmMLCK matches the twitchin consensus at 15 positions and the complete copy of motif II in csmMLCK matches the twitchin consensus at 25 positions. *c*, The twitchin motif II consensus is compared with the following sequences of members of the C2 set of the immunoglobulin superfamily of proteins: N-CAM, fourth domain[24]; myelin-associated glycoprotein (MAG), second domain[44]; PDGFR, third domain[45], and the immunoglobulin Fc receptor (FcR) first domain[46]. Residues identical to the twitchin consensus are shaded. Also displayed is a consensus for the immunoglobulin C2-set domains (modified from ref. 23). Upper-case letters denote the most strongly conserved amino acids, and the lower-case letters denote the less strongly conserved residues at various positions. A box encloses one region particularly highly conserved between motif-II copies.

Most probably twitchin associates with the thick filament, as it is found in the myosin-containing A bands and co-localizes with myosin in mutants in which muscle structure is abnormal[7]. The regular spacing and pattern of the motifs throughout much of the protein are well suited for the interaction with the repeated structure of the thick filament, which consists of a regular staggered array of myosin rods and paramyosin. Furthermore, both the myosin rod and paramyosin are composed of tandem copies of a 28-amino-acid motif estimated to be 42-Å long[33,34], a size similar to that of an immunoglobulin domain and perhaps motif II as well. But the regularity of the motifs is disrupted in several places, including two occurrences of motif-I triplets, one instance of a motif-I singlet, and two occurrences of motif II doublets (Fig. 1*d*). Whether these represent adaptations to fixed irregularities in thick filament structure or relaxed functional requirements of the protein is unclear; note that deletions in the gene that maintain the reading frame, yet disrupt the domain structure, can result in proteins with nearly normal function[35].

The association of the protein with the thick filament may localize the kinase domain near the myosin heads on the surface of the filament. This also means, however, that neither the kinase nor its substrate myosin can diffuse within the cell. Yet each kinase domain must act on many myosins, as there is estimated to be only one mole of twitchin per 10–50 moles of myosin. Perhaps the kinase domain has enough flexibility to allow it to act on many myosins. Alternatively, the repeated domains themselves could play a part in regulation. If, indeed, the protein interacts along the long axis of the filament, it could serve to coordinate the activity of many myosins, in a manner analogous to the way in which tropomyosin regulates multiple actins. Also, like tropomyosin, the molecule could propagate changes in activity generated by the kinase domain down the filament, or calcium levels could directly alter the conformation of the repetitive part of the molecule. Consistent with these ideas is the finding that twitchin is required in near stoichiometric amounts; the loss of just half of the *unc-22* activity results in detectable twitching.

Does twitchin also have a fundamental role in thick filament assembly? The myofilament lattice is disrupted in nearly all *unc-22* mutants, but the numbers of thick filaments, even in the complete absence of twitchin, are about normal[2]. Furthermore, the assembly of these filaments into a sarcomere can be normal in the absence of twitchin, provided that certain missense mutations are present in the myosin head region[4,5]. Twitchin seems, therefore, to be unnecessary for either normal thick-filament formation or normal sarcomere assembly; a structural role for twitchin may yet, however, be found. We suggest instead that this unusually large protein has an important role in regulating the contraction–relaxation cycle. □

ACKNOWLEDGEMENTS. We thank Alan Coulson and John Sulston for identifying and supplying cosmid C32B3, Steve L'Hernault for clones pSL4 and pSL7, Barbara Meyer and Robert Barstead for cDNA libraries, Sheree Benner for technical assistance, Stephen Rioux for help in isolating the cDNA clone LSR1, John Trinick, Norma Olson and Anthony Means for allowing us to cite their unpublished results, and Mark Johnston, Tim Schedl, John Cooper and Steve L'Hernault for comments on the manuscript. This work was supported by the NIH (G.M.B. and R.H.W.).

Is Cygnus X-3 blowing bubbles?

A. Achterberg

Centre for High Energy Astrophysics, NIKHEF-H, Kruislaan 409,
1098 SL Amsterdam, The Netherlands

CYGNUS X-3, one of the brightest X-ray sources in the Galaxy and perhaps also a source of very-high-energy (TeV) photons or particles, is thought to be a close binary system (orbital separation $\sim 10^{11}$ cm and period 4.8 h) whose emission is powered by accretion of mass from a main-sequence star like the Sun onto a neutron star, or possibly a black hole. The X-ray luminosity, $L_x \sim 10^{38}$ erg s^{-1}, implies a radiation rate near the Eddington limit. Recent radio observations of Cyg X-3 (ref. 1) have revealed extended radio lobes on a scale of ~0.3 pc, elongated in the same direction in which clouds of relativistic plasma, discovered by very-long-baseline interferometry observations[2-4] during radio outbursts, are ejected from the binary system. I argue here that the extended radio lobes can be understood as bubbles blown into a dense interstellar medium by the cumulative energy of the bursts from the central object. If this is correct, the extended lobes of Cyg X-3 would have to be ~2,000 years old.

At radio frequencies, Cyg X-3 shows strong, irregularly spaced bursts of emission in which the flux rises by a factor of 100–1,000 above the typical level[5]. The mean interval between bursts is $p_b \sim 120$ days. The bursts can be interpreted as synchrotron radiation from an expanding cloud of relativistic electrons in a magnetic field of 10^{-2} G. Very-long-baseline interferometry (VLBI) observations[2-4] during bursts show an expanding elongated radio-frequency source on a scale of 10^{14} cm. Assuming a distance to Cyg X-3 of 10 kpc, the projected expansion velocity is $V_{exp} \approx 0.3$–$0.4\ c$. The minimum energy per burst, U_b, required to power the emission is about 10^{44} erg (ref. 7), and the associated average luminosity L_b is $U_b/p_b \approx 10^{37}$ erg s^{-1}, which is about 0.1 L_x. The recently discovered[1] extended radio lobes have a linear extent of $D \approx 10^{18}$ cm. The extended lobes are elongated in the direction of the VLBI-detected expansion, which suggests a causal connection with the bursts.

The physical properties of the extended lobes calculated assuming that the radio emission is synchrotron radiation are summarized in Table 1. The minimum energy, U_{min}, stored by relativistic electrons and magnetic fields in the lobes is estimated to be $\sim 10^{45}$ erg. This energy could be supplied by the bursts in a time $t_{min} \approx U_{min}/L_b \approx 3$ yr. This energy could be supplied by the bursts in a time $t_{min} \approx U_{min}/L_b \approx 3$ yr. This is of the same order of magnitude as the dynamical timescale $t_{dyn} \approx D/V_{exp}$ derived from the VLBI-detected source expansion. In contrast, the radiation-loss time of the synchrotron electrons, t_{loss}, is $\sim 10^6$ yr. The fact that $t_{loss} \gg t_{dyn}$, t_{min} suggests that most of the energy supplied to the lobes by the central source is expended in driving the expansion of the lobes, rather than in building up the internal energy density and compensating for synchrotron losses. In that case, the lobes must be much older than the simple estimate t_{min} would suggest.

I propose a model for the extended lobes that is analogous to the formation of bubbles in the interstellar medium by stellar winds. It differs from conventional models of radio-lobe formation used in the context of active galaxies and quasars in the assumption that the momentum flux of the outflow is not well collimated as in a jet with constant cross-section, but instead is distributed over an area scaling as D^2, where D is the linear extent of the source. This would be the case for instance in a conical jet with a fairly large constant opening angle, or in a quasi-spherical expansion.

On timescales $t \gg p_b$ the expansion is driven by the cumulative energy of the bursts. A self-similar solution describes a shock propagating into the interstellar medium with typical radius[8] $R(t) = \alpha(L_b/\rho)^{1/5} t^{3/5}$, where ρ is the density of the interstellar medium, t is the age of the source and α is a numerical constant of the order of unity. The hot interior of the bubble and the shocked interstellar medium are separated by a contact discontinuity at radius $R_{cd} \approx 0.83\ R(t)$. For spherical symmetry (opening angle near 4π), $\alpha \approx 0.88$ during the initial adiabatic phase of the expansion and $\alpha \approx 0.76$ after the shell of swept-up interstellar medium has collapsed through internal cooling and radiates efficiently. The detailed shape of the lobe depends on the (unknown) angular distribution of the momentum flux driving the expansion, and can be calculated using a generalized Kompaneets approximation[9,10]. The lobes will be elongated along the direction of the beamed outflow from the central source, as observed.

Given the observed size, D, of the extended lobes, one can use the above expansion law to estimate the age of the source:

$$t\,(\text{yr}) \approx 1.5 \times 10^3 \alpha^{-5/3} D_{18}^{5/3} n_2^{1/3} L_{37}^{-1/3} \tag{1}$$

where D_{18} is the linear size of the source in units of 10^{18} cm. n_2 is the number density in the interstellar medium in units of 100 cm^{-3} and L_{37} is the driving luminosity in units of 10^{37} erg s^{-1}. The age of a few thousand years for the extended source is much less than the evolutionary timescale for a close binary system ($\geqslant 10^6$ yr). This suggests that the bursts driving the expansion are a fairly recent phenomenon in Cygnus X-3. The expansion velocity of the lobes is $\dot{D} = 1.3 \times 10^2 \alpha^{8/3} L_{37}^{1/3} n_2^{-1/3} D_{18}^{-2/3}$ km s^{-1}, and the internal pressure in the lobes is roughly equal to the pressure behind the strong shock, $P_s \approx (3/4)\rho\dot{D}^2 \approx 2 \times 10^{-8} \alpha^{16/3} n_2^{1/3} L_{37}^{2/3} D_{18}^{-4/3}$ erg cm^{-3}. This yields a total thermal energy U_{th} of the lobes of the order of $(3/2)P_s \times (4\pi D^3/3) \approx 10^{47} \alpha^{16/3} L_{37}^{2/3} n_2^{1/3} D_{18}^{5/3}$ erg. Comparing U_{th} with the minimum energy U_{min} needed to explain the extended synchrotron emission, I estimate that ~1% of the internal energy must reside in the relativistic electrons and magnetic fields responsible for the synchrotron emission. The total energy U_{tot} supplied to the lobes, including the kinetic energy of the swept-up interstellar material, is $L_b t = 4.5 \times 10^{47} \alpha^{-5/3} D_{18}^{5/3} L_{37}^{2/3} n_2^{1/3}$ erg $\approx 4.5 \times 10^2 \alpha^{-5/3} U_{min}$.

In its lifetime the extended source has swept up interstellar gas with total mass $M_s(\text{g}) \approx (4\pi/3)\rho D^3 \approx 10^{33} n_2 D_{18}^3$. The swept-up gas directly behind the shock has a temperature $T_+\,(\text{K}) \approx (3\mu m_H/16 k_B)\dot{D}^2 = 5 \times 10^5 \alpha^{16/3} L_{37}^{2/3} n_2^{-2/3} D_{18}^{-4/3}$, where $\mu \approx 1.4$ is the mean relative molecular mass per hydrogen atom, m_H is the mass of a hydrogen atom and k_B is the Boltzmann constant. Radiation losses per unit volume $C(T)$ in this hot gas of ionized hydrogen and multiply ionized other elements are $n_e n_p \Lambda(T)$, where the cooling function $\Lambda(T) \approx 1.6 \times 10^{-22} T_6^{-0.6}$ erg cm^3 s^{-1}, T_6 being the temperature of the gas in units of 10^6 K. Here n_e and n_p are the electron and proton densities. Cooling is primarily due to line emission for $T \leqslant 10^7$ K. Defining a net compression ratio $n_s/n \equiv r$ for the swept-up gas and taking $n_e \approx n_p \approx n_s$, the typical cooling time behind the shock, $t_C \approx 3 n_s k_B T/(2C(T)) \approx 1.5 \times 10^2 (T)_6^{1.7} r^{-1} n_2^{-1}$ yr. This is shorter than the age of the lobes provided that $rn_2 \geqslant 0.1$, so that it is likely that the shocked interstellar material has collapsed into a thin shell, or is in the process of doing so.

The energy advected into the shell across the shock per unit time, $L_s \approx 4\pi D^2 \times (\rho\dot{D}^3/2) \approx 2\pi\alpha^5(3/5)^3 L_b \equiv \varepsilon L_b$, is largely radiated away ($\varepsilon \approx 0.3$ if $\alpha \approx 0.76$, and L_s is the luminosity of the shocked material). The hot layer of ionized hydrogen and multiply ionized ions cools by radiating most of its energy in the ultraviolet at wavelengths <912 Å. At a column density of $N \approx 10^{17}$ cm^2 behind the shock, the temperature reaches $T \approx 10^4$ K and a recombination zone begins which reabsorbs this ionizing ultraviolet radiation. This zone therefore radiates with a total luminosity of about L_s, cooling through optical and ultraviolet radiation[11,12]. A typical cooling rate has $\Lambda_{rec} \approx 2 \times 10^{-23}$ erg cm^3 s^{-1} (refs 13, 14). The thermal free-free emission from the dense shell comes primarily from the recombination zone. The free-free emissivity per unit volume is $n_e n_p \Lambda_{ff}(T)$, with a free-free cooling function $\Delta_{ff}(T) \approx 2.4 \times 10^{-25} T_4^{1/2}$ erg cm^3 s^{-1}, where T_4 is the temperature of the recombination zone in units of 10^4 K. The total free-free luminosity can be estimated as $L_{\mathrm{ff}} \approx \Lambda_{\mathrm{ff}}(T)\varepsilon L_{\mathrm{b}}/(\Lambda_{\mathrm{rec}} + \Lambda_{\mathrm{ff}}(T)) \approx 4\times 10^{34} T_4^{1/2}(\varepsilon/0.3)L_{37}$ erg s^{-1}. The free-free emission from the hot region directly behind the shock is about a factor of 100 less intense. At low freqencies ($h\nu \ll k_{\mathrm{B}}T$) the monochromatic free-free emission flux $(S_\nu)_{\mathrm{ff}}$ at the Earth for an assumed distance of $d = 10$ kpc is about $(h/k_{\mathrm{B}}T)(L_{\mathrm{ff}}/4\pi d^2) \approx 2(\varepsilon/0.3)L_{37}$ mJy. Extinction can be neglected at a wavelength of 6 cm. This is about a factor of two less than the observed extended flux density. It therefore seems likely that a significant part of the radio emission is synchrotron radiation, as was assumed by Strom *et al.*[1]. This interpretation is supported by their detection of (partial) polarization of the 6-cm emission. The relative contribution of thermal free-free radiation will remain uncertain until multi-frequency observations determine the spectrum of the radio emission from the extended lobes.

The relativistic electrons filling the lobes have probably not been produced directly by the bursts. A power-law distribution of relativistic electrons—$(\mathrm{d}N/\mathrm{d}\gamma) \propto \gamma^{-s}$ where γ is the Lorentz factor (integrated over volume)—that are created at an individual burst in a volume V_0, carrying a fraction f of the total burst energy U_{b}, contributes a relativistic-electron energy $U_{\mathrm{e}} = fU_{\mathrm{b}}(V/V_0)^{-(s-1)/3}$ after adiabatic expansion into the volume V of the extended lobes. The VLBI-detected clouds have a volume $V_0 \leqslant 10^{45}\ \mathrm{cm}^3$, whereas the observed spectrum is consistent with[4,7] $s \approx 2$. After expansion into the whole lobe volume $V \approx 10^{54}\ \mathrm{cm}^3$, the remaining relativistic-electron energy per burst is $U_{\mathrm{e}} \leqslant 10^{-3} fU_{\mathrm{b}} \approx 10^{41} f(U_{\mathrm{b}})_{44}$ erg (where $(U_{\mathrm{b}})_{44}$ is the burst energy in units of 10^{44} erg). This is four orders of magnitude less than the relativistic-electron energy present in the lobes if the observed 6-cm emission has a significant non-thermal component. This excludes the possibility that the extended lobes are adiabatically expanding, optically thin synchrotron clouds created by a single large burst in the central object about three years ago. The energy of the cloud accumulated from all the bursts in a time $t_{\mathrm{loss}} > t \gg p_{\mathrm{b}}$ is $U_{\mathrm{c}} \approx (t/p_{\mathrm{b}})U_{\mathrm{e}} = f(V/V_0)^{-(s-1)/3}L_{\mathrm{b}}t = 10^{-3}fU_{\mathrm{tot}}$. For f of the order of unity, $U_{\mathrm{c}} \approx U_{\mathrm{min}}$, but it seems unlikely that all the energy in the bursts resides in relativistic electrons.

The total monochromatic synchrotron luminosity of the lobes that is due to the accumulated relativistic electrons is $S_\nu = (t/p)(B/B_0)^{(s+1)/2}(V/V_0)^{-(s-1)/3}S_\nu(\mathrm{burst})$. The observations of the bursts are consistent with $B_0 \approx 0.1$ G, whereas the lobes have $B_{\mathrm{eq}} \approx 10^{-4}$ G. Here B_0, B and B_{eq} are the magnetic field in the VLBI clouds, the extended lobes and the equipartition field respectively. This gives $S_\nu \approx 10^{-4}S_\nu(\mathrm{burst}) \leqslant 1$ mJy, as the strongest bursts have $S_\nu(\mathrm{burst}) \approx 10$ Jy. This is at least a factor of five less than the observed flux density (see Table 1). Some parameters, however, are quite uncertain—in particular the energy density in the lobes and the magnetic field strength B, which are derived from the minimum-energy assumption. These estimates imply that some reacceleration and/or fresh production of relativistic electrons is required in the lobes to partly compensate for expansion losses, which increases the synchrotron luminosity.

An efficient acceleration mechanism that is likely to operate in the lobes is diffusive shock acceleration[15]. Particles will be accelerated at the strong exterior shock that encloses the lobes or at shocks generated when clouds formed at each burst collide with the dense shell of shocked interstellar material behind that exterior shock. The mean energy gain in this process of a particle with Lorentz factor γ, diffusing with spatial diffusion coefficient K, at a strong shock with propagation velocity u_{s} is

$$\frac{1}{\gamma}\left(\frac{\mathrm{d}\gamma}{\mathrm{d}t}\right) \approx \frac{u_{\mathrm{s}}^2}{4\langle K\rangle} \tag{2}$$

TABLE 1 Observational parameters

Distance Cyg X-3: 10 ± 2 kpc.
X-ray luminosity: $L_{\mathrm{X}} = 10^{38}\ \mathrm{erg\ s^{-1}}$
Mean 6-cm flux density associated with burst: $S_\nu(\mathrm{burst}) \approx 5$ Jy
Extended 6-cm flux density at Earth: $S(\nu = 4.9\ \mathrm{Ghz}) = 4.5$ mJy
Radio luminosity of extended lobes: $L_{\mathrm{r}} = 3\times 10^{30}\ \mathrm{erg\ s^{-1}}$
Diameter of extended lobes: $D = 0.3\ \mathrm{pc} = 10^{18}$ cm
Minimum energy: $U_{\mathrm{min}} = 10^{45}$ erg
Equipartition field: $B_{\mathrm{eq}} = 10^{-4}$ G

Here $\langle K\rangle$ is a mean spatial diffusion coefficient, defined by $\langle K\rangle = K_- + 4K_+$. The subscripts $-$ and $+$ denote typical values in the medium upstream and downstream of the shock. The relativistic electrons diffuse by gyro-resonant scattering from magneto-hydrodynamic waves. The associated diffusion coefficient is $K = (cr_{\mathrm{g}}/3)\ I(k_{\mathrm{res}})^{-2}$, where $r_{\mathrm{g}} = \gamma m_{\mathrm{e}}c^2/eB = 1.6\times 10^7\gamma B_{-4}^{-1}$ cm is the gyroradius of an electron with Lorentz factor factor γ and $I(k_{\mathrm{res}}) \equiv \delta B(k_{\mathrm{res}})/B$ is the relative magnetic amplitude of the waves at the resonant wavenumber $k_{\mathrm{res}} \approx 1/r_{\mathrm{g}}$. For strong turbulence ($\delta B(k)/B \approx 1$ at all scales), one has $K = K_0\gamma$, where $K_0 = m_{\mathrm{e}}c^3/3eB \approx 10^{18}B_{-4}^{-1}\ \mathrm{cm^2\ s^{-1}}$ is the diffusion coefficient of a particle with $\gamma \approx 1$. Electrons injected into the acceleration region with $\gamma \approx 1$ gain energy according to $\gamma(t) \approx 1 + u_{\mathrm{s}}^2t/(4\langle K_0\rangle)$. This means that electrons radiating by the synchoton mechanism at $\lambda = 6$ cm with a shock Lorentz factor $\gamma_{\mathrm{s}} \approx 1{,}000$ can be accelerated in a time $t_{\mathrm{acc}} \approx 8\gamma_{\mathrm{s}}K_0/u_{\mathrm{s}}^2 \approx 10^6(K_0)_{18}/(u_{\mathrm{s}})_8^2$ s, where I have assumed that $\langle K_0\rangle \approx 2K_0$ ($(u_{\mathrm{s}})_8$ is the shock propagation velocity in units of $10^8\ \mathrm{cm\ s^{-1}}$ and $(K_0)_{18}$ is the spatial diffusion coefficient in units of $10^{18}\ \mathrm{cm^2\ s^{-1}}$). Acceleration at the outer shock with $(u_{\mathrm{s}})_8 \approx 0.1$ can proceed to the required energies in $\sim 3(K_0)_{18}$ yr. This is much less than the age of the source provided $K_0 \leqslant 10^{21}\ \mathrm{cm^2\ s^{-1}}$, allowing for less-efficient scattering by weak turbulence with $\delta B(k_{\mathrm{res}})/B \approx 0.03$. Alternatively, if the central source ejects clouds moving ballistically, as does SS433[16], these clouds will collide with the outer dense shell of the lobes. This will also result in the formation of shocks when these individual clouds break up. With an assumed cloud velocity $V_{\mathrm{c}} \approx V_{\mathrm{exp}} \approx 0.35c$ and a cloud size r_{c}, the maximum time available for acceleration at such a collision is $r_{\mathrm{c}}/V_{\mathrm{c}} \approx 10^6(r_{\mathrm{c}})_{16}$ s (where $(r_{\mathrm{c}})_{16}$ is r_{c} in units of 10^{16} cm). As u_{s} is expected to be of the order of $V_{\mathrm{exp}} \sim 10^{10}\ \mathrm{cm\ s^{-1}}$, this is more than enough to (re)accelerate the electrons to the required GeV energies. It therefore seems likely that the modest amount of reacceleration required in this model can be supplied by diffusive shock acceleration, even with a low level of turbulence $\delta B(k_{\mathrm{res}})/B \approx 0.1$. The maximum energy that can be attained by electrons from continuously operating shock acceleration at the outer shock is determined by synchrotron losses. Writing these losses as $(\mathrm{d}\gamma/\mathrm{d}t)_{\mathrm{synch}} = -\gamma^2/\tau$, with $\tau = 6\pi m_{\mathrm{e}}c/\sigma_T B^2 = 2\times 10^9\ B_{-4}^{-2}$ yr (here σ_{T} the Thomson cross-section) and balancing them with the energy gain that is due to shock acceleration (equation (2)) (assuming as before that $\langle K\rangle = 2K_0\gamma$) I obtain $\gamma_{\mathrm{max}} \approx (u_{\mathrm{s}}^2\tau/8K_0)^{1/2} \approx 10^7(u_{\mathrm{s}})_8 B_{-4}^{-1}(K_0)_{18}^{-1/2})$. Expansion losses in the self-similar flow $(\mathrm{d}\gamma/\mathrm{d}t)_{\mathrm{exp}} \approx -(\dot{D}/D)\gamma \approx -3\gamma/5t$ become important at $\gamma \approx 5u_{\mathrm{s}}^2t/24K_0 \approx 10^8(u_{\mathrm{s}})_8^2\alpha^{-5/3}D_{18}^{5/3}n_2^{1/3}L_{37}^{-1/3}(K_0)_{18}^{-1}$. □

Ultra-low-frequency variability in a simple atmospheric circulation model

I. N. James & P. M. James

Department of Meteorology, University of Reading, Reading RG6 2AU, UK

To assess the inherent variability of atmospheric flow, we have carried out extended runs of a primitive-equation model of the global troposphere. The longest-period forcing that we explicitly included was the annual cycle, yet the largest-scale structures in the flow were variable on much longer timescales, with maximum variability on periods of 10–40 years. This variability was generated internally by the nonlinear dynamics of the atmospheric flow. Forcings by slow variations of such quantities as sea surface temperature or incoming solar radiation were excluded. The results show that apparent correlations with the sunspot cycle[1–3] could be spurious. They also indicate that attempts to monitor systematic climate change require circulation statistics for periods longer than 40 years, and that studies of climate sensitivity based on global circulation models require integrations of at least that length.

The observed variability of atmospheric flow at low frequencies may be due either to the inherent, internally generated unsteadiness of that flow, or to external influences in the form of varying boundary forcing, changing solar radiation or to changes of atmospheric composition. The relative contribution of internal and external sources of variability is still uncertain. Arguments based on linear theories of instability and on the known limits of deterministic predictability suggest that internal variability dominates for periods less than 10–20 days. It is frequently assumed that external causes must be sought for lower-frequency variations. Certainly there has been a degree of success in relating part of the observed interannual variance to slowly varying patterns of sea surface temperature. The nonlinearity of atmospheric flow does not necessarily mean, however, that its behaviour is completely random on the longer timescale. Coherent and relatively long-lived structures can arise. Extreme regularity in highly nonlinear flow is well known in experiments on rotating convecting fluids[4], and long-lived coherent blocking patterns are observed in the atmosphere[5]. Here we show that internally generated variations of much lower frequencies than have previously been assumed dominate the spectrum of planetary-scale structures in an atmospheric model. The results imply that a degree of regularity underlies the apparently random fluctuations of the circulation.

We used a global version of the spectral primitive-equation model described in ref. 6. We used five equal mass layers in the vertical. The smallest horizontal scale included was equivalent to 21 wavelengths around the globe (wavenumber 21); this implies a smallest resolved scale of ~700 km, and is similar to the resolution of many operational global-circulation models. The model handles the nonlinear dynamics of the atmosphere in a relatively sophisticated manner, representing the large-scale circulation systems of both the tropics and mid-latitudes explicitly.

We modelled the effects of diabatic heating and friction by simple linear terms so that we could carry out extremely long integrations at comparatively modest cost. The atmospheric circulation was driven by a term in the thermodynamic equation that relaxed the temperature towards a 'radiative–convective equilibrium' on a timescale of 15 days. The solstice distribution of the equilibrium temperature is shown in Fig. 1*a*. Such a state is unstable, particularly to baroclinic instabilities in the middle latitudes which convert potential energy associated with the meridional temperature gradients into the kinetic energy of the atmospheric circulation. This energy conversion is eventually balanced by the destruction of kinetic energy by friction at the Earth's surface. We modelled friction by a simple 'Rayleigh drag law' in the lowest model layer. A force $-\mathbf{v}/\tau_d$ acts on the air in the lowest layer, where $\mathbf{v}$ is the horizontal wind vector and τ_d a timescale, which we chose to be one day. We varied the pole-pole radiative equilibrium temperature difference sinusoidally to represent the seasonal cycle. The model included no moisture (except implicitly, by the definition of the radiative-convective equilibrium state) and the lower surface was uniform with no mountains or heat sources and sinks.

The mean temperature structure at the solstices is shown in Fig. 1*b*. The atmospheric circulation has increased the static stability and reduced the meridional temperature gradients by transporting heat upwards and polewards. Further discussion of the mean global circulation of this model and of its sensitivity to the imposed parameters is given in ref. 6.

The variability of the large-scale atmospheric flow is illustrated by spectra showing the frequency variation of certain coefficients of the spherical harmonic Y. We obtained the spectra by saving the spherical harmonic coefficients averaged with respect to pressure, every 10 (model) days, and applying a fast Fourier transform to the data for the last 96 years of the run. We excluded the first few years of the run to eliminate any initial transient effects. Figure 2*a* shows the spectrum of the Y_1^0 temperature coefficient. This is a measure of the inter-hemispheric

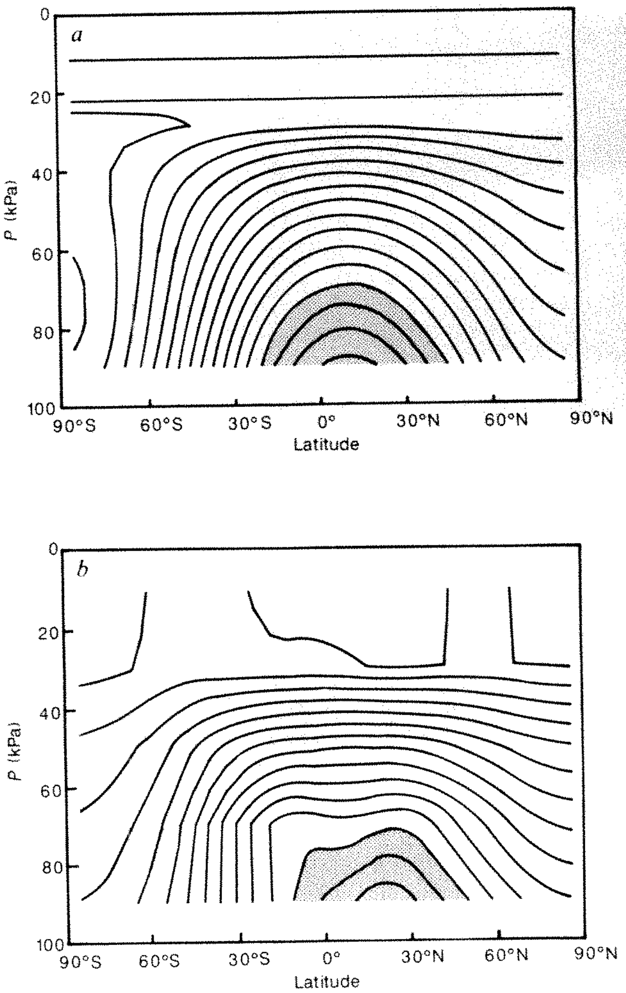

FIG. 1 Latitude–pressure cross-sections showing the zonal mean temperature distribution in *a*, the radiative–convective equilibrium state at the solstices and *b*, the model-generated solstice climatology. Contour interval 5 K, values in excess of an arbitrary reference temperature shaded.

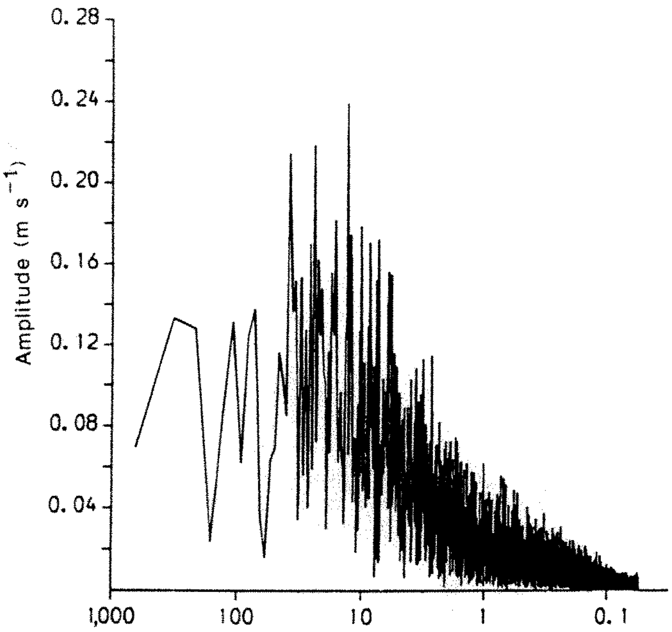

FIG. 4 As Fig. 2*b*, but for the 648-yr constant solstice calculation.

We fitted an autoregressive model to the time series of Y_1^0 coefficients. A 'red-noise' spectrum, with maximum variability at zero frequency gave the best fit. Standard statistical tests demonstrate the sharp peaks close to the period of the solar cycle are not *a posteriori* statistically different from the red-noise background. Rather, the spectra seem to be characterized by broad peaks with decadal periods. We extended the constant-solstice run to 648 years to test this suggestion. The spectrum of the Y_1^0 vorticity coefficient is shown in Fig. 4. A number of rather sharp peaks are seen in the range 10–40 years; the smoothed spectrum peaks in this range, and falls off towards both lower and higher frequencies. The maximum variability is clearly located within this range of periods.

The internal variability of the zonal mean part of the atmospheric circulation is large, on timescales as long as are currently available in accurate global data sets or in runs of global-circulation models. There is no reason to appeal to forcings external to the atmosphere (for example, solar forcing) to account for ultra-low-frequency variability. Models such as ours, with sophisticated atmospheric dynamics but simplified representation of other processes, are a benchmark against which to measure the ultra-low-frequency variability of more complex climate models. ☐

Critical currents near 10^6 A cm^{-2} at 77 K in neutron-irradiated single-crystal $YBa_2Cu_3O_7$

R. B. van Dover*, E. M. Gyorgy*, L. F. Schneemeyer*, J. W. Mitchell*, K. V. Rao†, R. Puzniak† & J. V. Waszczak*

THE defects in as-grown bulk $YBa_2Cu_3O_7$ have been shown to act as weak flux pinning sites, leading to a reversible magnetization[1], magnetization decay[2] and non-zero resistivity[3] in moderate magnetic fields at temperatures near the transition temperature, T_c. These effects limit the technological utility of the as-grown material[3]. This is not entirely surprising, as both single crystals and polycrystalline materials are grown under conditions expected to minimize the defect density, but the weak pinning in these materials has nevertheless raised the issue of a possible intrinsic limitation to the critical current density. Here we report the attainment of a critical current density, J_c, of $\sim 6\times10^5$ A cm^{-2} at 77 K and 9 kOe, in a single crystal of $YBa_2Cu_3O_7$ irradiated with fast neutrons to introduce defects. (In both irradiated and unirradiated crystals, the critical current density was inferred by measuring the magnetic moment resulting from an induced persistent current.) This hundredfold enhancement of J_c relative to unirradiated crystals demonstrates that artificially induced defects can act as strong flux pinning sites, and analysis of the defects should increase our understanding of flux pinning in high-T_c superconductors.

Thin films, in which we expect both different defects and a far higher defect density, can sustain supercurrents of $>4\times 10^5$ A cm^{-2} at 77 K and 20 kOe, with low dissipation levels[4] (measured by magnetization). Until now, such high values have not been reported in bulk $YBa_2Cu_3O_7$. Various methods of artificially increasing the defect density have been tried, including ion irradiation[5,6] and cation substitution, but the critical current density at 77 K has not been significantly enhanced.

Fast neutron irradiation[7–11] has also been used, with results ranging from negative to promising. Küpfer *et al.*[11], for example, report a twentyfold increase in the intragranular J_c of polycrystalline $YBa_2Cu_3O_7$ at 40 K and 15 kOe. As these ceramics are prepared using a high-temperature sintering step, the intragranular defects, and hence J_c, are similar to those of single crystals[12]. Wisniewski *et al.*[10], found a twentyfold increase in the magnetization of ceramic at 77 K after neutron irradiation, but the intragranular J_c cannot be inferred from the reported data. Fleischer *et al.*[13] found a similar twentyfold increase after irradiation of uranium-doped $YBa_2Cu_3O_7$ with thermal neutrons, and were able to infer critical currents of $\sim 10^5$ A cm^{-2} at 77 K. Previous work on single crystals[8] has suggested at best a twofold increase in J_c, even though a procedure similar to ours was used.

Our single crystals were prepared as described previously[14]. Extensive measurements on these crystals have convinced us that they are uniform, homogeneous, reproducible and generally of high quality. They were encapsulated in silica tubes and irradiated with fast ($E > 1.0$ MeV) neutrons at the reactor facility of the University of Virginia, a facility which offers a high degree of shielding from slow neutrons (Cd ratio = 1.0). The neutron fluence was 7.9×10^{16} cm^{-2}.

Figure 1 shows the magnetization of an irradiated crystal during cooling in a 30-Oe applied field ($H \parallel c$ axis). The transition temperature is unchanged from the unirradiated value (89 K) and the sample shows no low-temperature anomalies which might indicate extensive second-phase regions. (The low level of flux expulsion results from the thin-plate geometry.) Zero-field-cooled measurements show that at low temperatures the sample exhibits essentially complete diamagnetic shielding. These results are consistent with previous studies[8,9]. Magnetization loops ($H \parallel c$ axis), shown in Fig. 2, were obtained with a vibrating-sample magnetometer. Owing to the low critical current of the unirradiated sample, an ensemble of nominally identical crystals was measured to increase the signal-to-noise ratio. The limited number of samples has allowed us to measure only one irradiated crystal so far, so we cannot report on the reproducibility of the experiment. The magnetization of the irradiated crystal (at $H=0$) did not decay measurably over a time interval of ~30 s; this behaviour will be the subject of a further study. A crude estimate of the self-inductance of the sample is ~1 nH; thus, the inferred resistivity is in the range $\rho < 10^{-16}\ \Omega$ cm, assuming that the decay is dominated by a simple L/R time constant (where L is inductance and R resistance). The dimensions of the sample ($0.06 \times 0.08 \times 0.003$ cm) preclude a satisfactory estimate of critical-current anisotropy[15], as the broad face is in the a–b plane.

Transport measurements of J_c are both insensitive (to measure $10^{-16}\ \Omega$ cm at 10^6 A cm^{-2} with conventional equipment would require a crystal ~1 m long) and necessitate the application of a large current (for a typical cross-section of 0.06×0.003 cm, a current of 240 A would be required). But we can infer the critical current in the plane of the film ($J \parallel a, b$ axes) unambiguously using the critical-state model and a Bean-like interpretation. In this case, $J_c = 20\,\Delta M[f(1-f/3g)]^{-1}$ (ref. 15) where ΔM is the difference between the upper and lower magnetization branches at a given field, and f and g ($f<g$) are the face dimensions of the rectangular sample. Here, as throughout the paper, we use the practical units gauss, cm and amperes. At 9 kOe we measure $\Delta M^{\mathrm{irrad}} = 1{,}200$ G, so $J_c^{\mathrm{irrad}}(77\ \mathrm{K}, 9\ \mathrm{kOe}) = 6.2 \times 10^5$ A cm^{-2}. A similar analysis of the magnetization of the unirradiated sample yields $J_c^{\mathrm{unirrad}}(77\ \mathrm{K}, 9\ \mathrm{kOe}) = 6.5 \times 10^3$ A cm^{-2}. Measurements on an unirradiated sample broken from the same original crystal as the irradiated sample were noisy but consistent with the latter value. In these analyses, we assume that the currents flow through the entire sample, that is, that the sample is not granular. To check this, we note that the shielding field H^* required to reverse the direction of the circulating current is given by $H^* \approx 2\pi t J_c/5$, a value which depends only on the thickness, t, of the sample, and which has been empirically verified on many of our single crystals. The shielding field can be seen to be ~3 kOe, so $J_c \approx 8 \times 10^5$ A cm^{-2}. Unless the induced granularity coincidentally preserves the aspect ratio of the sample, this indicates that the induced currents flow throughout the sample. Note that if the sample were granular, the inferred intragranular critical current would be larger than 6×10^5 A cm^{-2} (inversely proportional to the characteristic length of a grain).

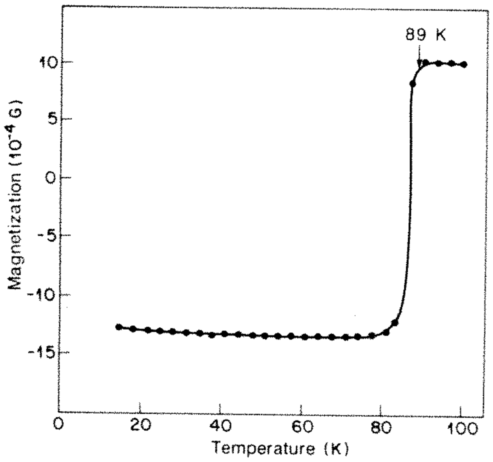

FIG. 1 Temperature dependence of the magnetization for the irradiated sample on cooling in a 30-Oe magnetic field. The absence of structure indicates a relatively homogeneous sample. The offset in magnetization above T_c is due to instrumental background.

We attribute the dramatic increase in J_c on irradiation to the introduction of pinning centres which inhibit flux motion. It is possible that the density of pinning centres has been increased, or that the pinning energy of each centre has increased, or both. Alternatively, the nature of the pinning may have changed, for example, by altering the electronic anisotropy. Note that the anomalous increase in J_c at low fields (>5 kOe) has been eliminated in the irradiated sample; a similar effect was noted previously in measurements[11] at 40 K, but the interpretation remains controversial. In any case, we emphasize that this magnetic measurement probes the sample with extreme sensitivity to dissipation, and that an effective criterion of $10^{-16}\ \Omega$ cm is sufficiently stringent for almost all technological applications.

The preceding discussion shows that flux creep is certainly not an intrinsic limitation on the use of bulk high-T_c superconductors. Radiation-induced defects are not expected to improve intergranular superconducting connections, as shown by studies on thin films[16], but in bulk materials not dominated by weak-link intergranular connections (for example, materials formed by melt-textured growth[17-19]), the artificially induced defects should dramatically enhance the critical current density at 77 K.

The structure of the defects introduced by neutron irradiation has not yet been determined. The defects apparently have a different effect than those produced by heavy-ion irradiation, which have so far given at most a twofold increase[6] in J_c at 77 K (in thin films). Irradiation by heavy ions creates a high density of defects strongly correlated along the tracks of individual ions. Because neutron collision cross-sections are small, neutron irradiation generates defects much more homogeneously

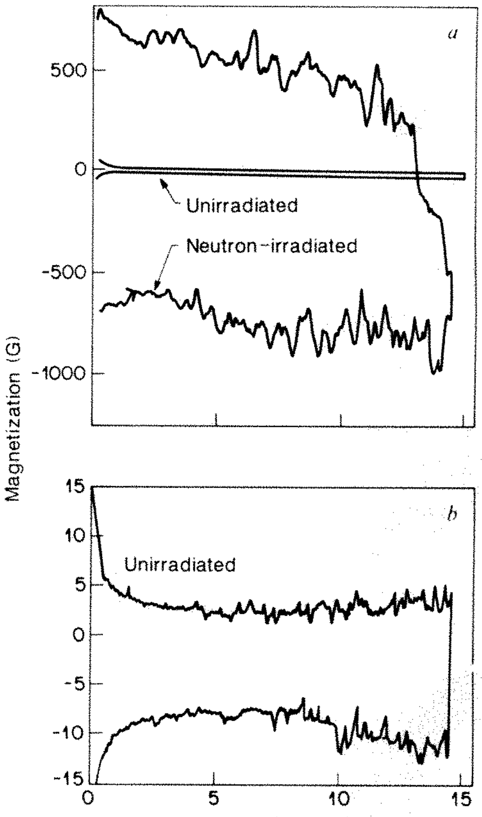

FIG. 2 *a*, Magnetization hysteresis loops of the unirradiated and irradiated sample. The large magnetizations observed in the irradiated sample imply a large circulating supercurrent. *b*, The hysteresis loop of the unirradiated sample on a more sensitive scale. The unirradiated sample is an ensemble of individual crystals, to increase the signal-to-noise ratio.

throughout the volume of our single-crystal samples, and with much lower local defect density. These distinctions may be important, but we also note that nominally identical neutron irradiation procedures have resulted in effects on critical current ranging from moderate enhancement to degradation. ☐

Water-level fluctuations of Lake Tanganyika in phase with oceanic changes during the last glaciation and deglaciation

Françoise Gasse, Vincent Lédée, Marc Massault & Jean-Charles Fontes

Laboratoire d'Hydrologie et Géochimie Isotopique, Bâtiment 504,
Université Paris-Sud, 91405, Orsay Cedex, France

THERE has been considerable controversy about the magnitude of fluctuations of the levels of Lake Tanganyika, the Earth's second deepest lake (1,470 m), following the discovery of submerged valleys extending down to 550 m below present lake levels[1]. These fluctuations register changes in the precipitation/(evaporation + evapotranspiration) ratio in a large equatorial–tropical area of catchment, south of the Equator. Here we report new palaeohydrological data, back to 40 kyr BP, from carbon dating of the total organic matter in two diatomaceous cores. The results constrain the vertical lake level fluctuations more than has hitherto been possible[2–5] and show that the fluctuations from 26 kyr BP are correlated with changes in global sea level and ice volume. Surprisingly fluctuations seem to be in phase with those of the African lakes north of the Equator, which are clearly linked to the Milankovitch mechanisms.

Lake Tanganyika (3°30′–9° S, 31°20′ E), a meromictic lake[6,7], contains ~18,800 km^3 of water[8]. The precipitation on the lake surface and surface runoff represents about 63% and 37% of the water input, respectively; evaporation (94%)[3,9] is the major loss of water. Surface outflow by the Lukula river controls the maximum (and present) lake level.

Core MPU XII (Figs 1 and 2), 1,013 cm in length, was collected in the southern basin where the lake is 422 m deep, and has been dated to 25,600 BP at its base[4]. Core MPU III (Figs 1 and 3), 1,123 cm in length, was taken at the depth of 130 m on the steep slope that separates the Cameron Bay from the southern basin. The sediments consist mainly of laminated or homogeneous diatomite.

Detailed results of quantitative diatom analyses and taxonomical discussion will be presented elsewhere. Here we focus on the water level indicators (Figs 2 and 3). Diatom biozones, based on the dominant taxa, appear in the cores (Fig. 4). We correlate them with diatom biozones previously established in core T2[2,3] which was collected close to core MPU XII (Figs 1 and 4). We have also deduced the ages of the Holocene events from core SD2 which was taken from the northern basin (Fig. 4).

We measured the stable isotope (^{13}C) contents of total organic matter (TOM) from samples of the core MPU III (Fig. 3) to evaluate the relative proportion of lacustrine and terrestrial organic matter[10]. The ^{13}C contents are close to −25‰ and the ^{14}C activity values (from accelerator mass spectrometry, AMS) thus did not require normalization[11].

Core MPU XII shows nine diatom biozones distributed in three major stages (Figs 2 and 4). During stage 1 (>25,600–21,700 yr BP), the lake was shallower than today, as indicated by the amount of *Cyclotella ocellata*, a facultative planktonic species commonly regarded as littoral[12]. This species predominates in biozones IA (>25,600–~24,500 yr BP) and IC (~22,500–21,700 yr BP). The scarcity of periphytic forms (attached on a submerged substrate) is, however, difficult to reconcile with very shallow environments, or with a massive transport of diatoms from the marginal zone. Modern analogues are not available for assemblages rich in *Cyclotella ocellata* in recent African lakes[13] although this species was common in the plankton of Ethiopian and Afar lakes during the late Pleistocene[14], such as Lake Abhé which was then 100–160 m deep[15]. Such a moderate depth at the MPU XII site would be compatible with both the low percentages of periphytic forms and with the absence of lamination which suggests that the top of the anoxic deep-water mass, presently lying at a depth of 100–150 m (ref. 6), was below the core site during the sedimentation of biozones IA and IC. In contrast, the laminated facies in biozone IB indicates a permanent water stratification. The relatively high proportion of planktonic forms and the permanency of *C. ocellata* are further indications of a moderate rise in water level centred around 24,000 yr BP.

Stage II (21,700–12,700 yr BP) corresponds to generally very shallow conditions. Periphytic diatoms (such as *Rhopalodia* spp.) became abundant. They are associated with sponge spicules and phytoliths which also reflect shallow environments. Few laminations are observed. The minimum water depth is recorded in biozone IIB by a peak of *Gomphonema clevei*, typically periphytic in modern East Africa[13]. The presence of intact frustules (connected valves) is a further indication that this species was growing *in situ* at the MPU XII site, which thus was located in the photic zone. This reveals a drop in water

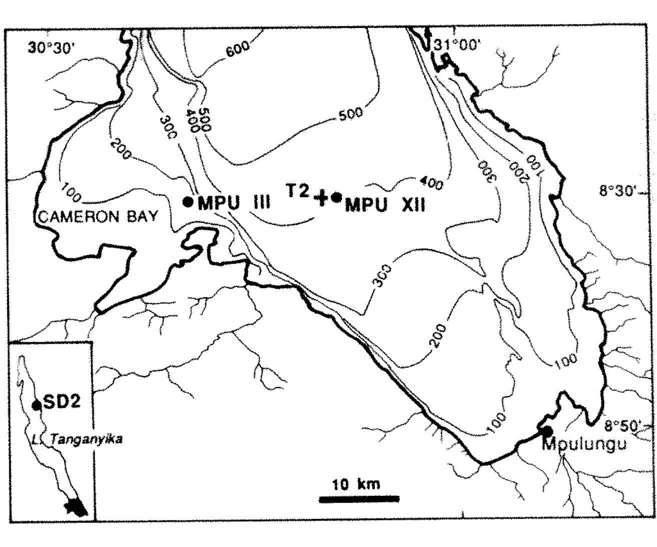

FIG. 1 Core location in Lake Tanganyika.

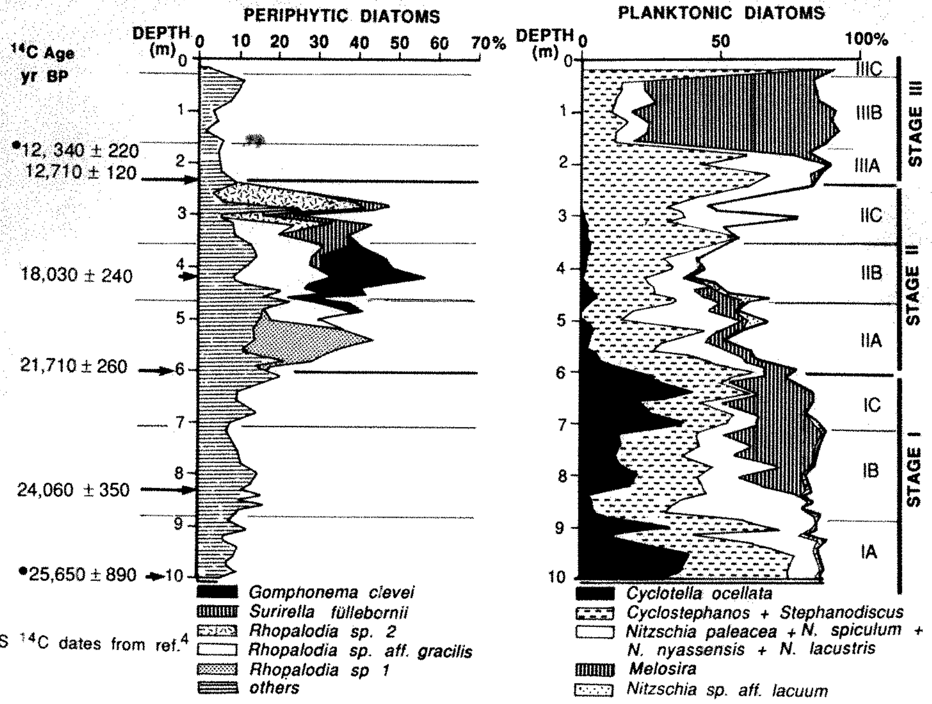

FIG. 2 Distribution of periphytic and planktonic diatoms along core MPU XII.

level of at least 350 m, more probably of about 400 m; this corresponds to a water volume that is −40 to −60% of the present value. The lake area/drainage area ratio was only 0.090–0.070 at that time compared to a present value of 0.137. The *Gomphonema* peak is dated at 18,030 ± 240 yr BP. This date differs significantly from that previously inferred from the ^{14}C-dated secular palaeomagnetic variations obtained in a Cameroon lake and extrapolated to Lake Tanganyika[4]. Whatever the causes for this discrepancy (for example, limited resolution of conventional ^{14}C ages from the Cameroon materials or delayed magnetic reorientation of fine particles in the highly porous sediments from Lake Tanganyika), such extrapolations seem to be unwarranted.

A generally positive lake water balance was established during Stage IIC (~16,000- > 12,700 yr BP), and the planktonic flora indicates that deep conditions were definitely restored to the lake shortly before 12,700 yr BP. This event was possibly preceeded by a first-positive oscillation around 14,500 yr BP, as suggested by a narrow peak of planktonic forms observed at a depth of 300 cm (Fig. 2). Deep-water conditions were maintained during Stage III, from 12,700 yr BP onwards. Perennial stratification occurred from 12,700- ~10,600 yr BP (base of biozone IIIA; Fig. 4) and from ~5000 yr BP, whereas biozone IIIB indicates deep mixing which may be due to upwelling events[5].

In core MPU III (Fig. 3), detritus deposits and disturbances are observed in the intervals 981–935 cm and 880–780 cm, and we therefore do not consider them in our palaeohydrological reconstructions. A discontinuity is suggested by the ^{14}C dates between ~30,000 and >12,300 yr BP, which may explain the absence of stages I and IIA–B.

Core MPU III confirms that the major regression ends around 13,000 yr BP. We assign the core section 780–760 cm to biozone IIC, and deep-water conditions were established before 12,300 yr BP (biozone IIIA) and maintained to the present. From >12,300–10,600 BP, a progressive decrease in the ^{13}C values (Fig. 3) may reflect the establishment of an arboreal vegetal cover on the catchment area[4], indicating increasing temperature and humidity[16]. The marked decrease at ~10,600 BP indicates

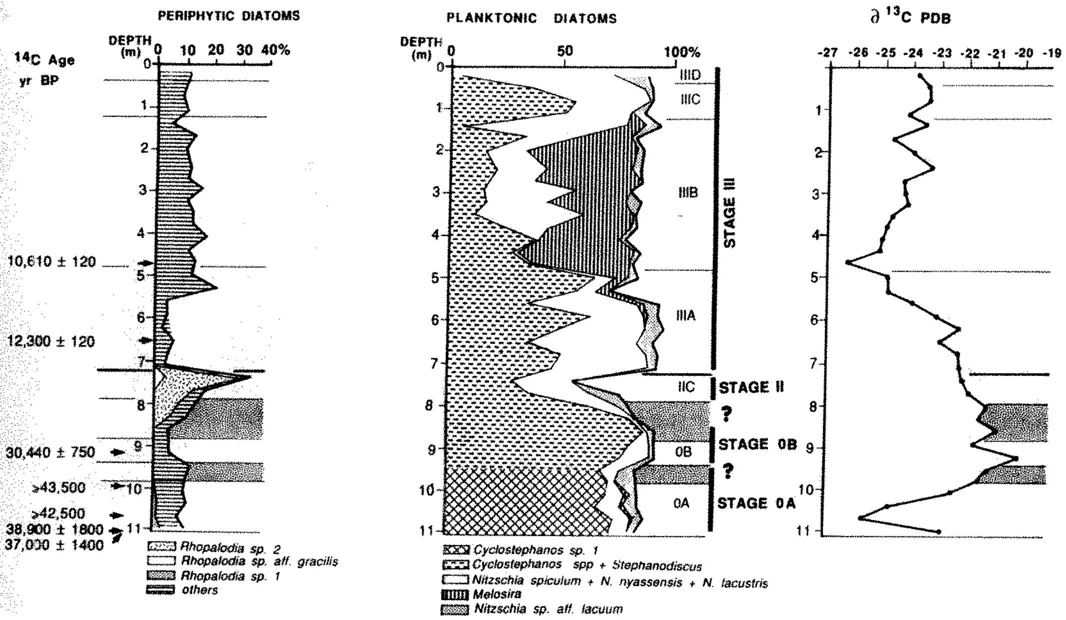

FIG. 3 Distribution of periphytic and planktonic diatoms, and ^{13}C content of total organic matter along core MPU III.

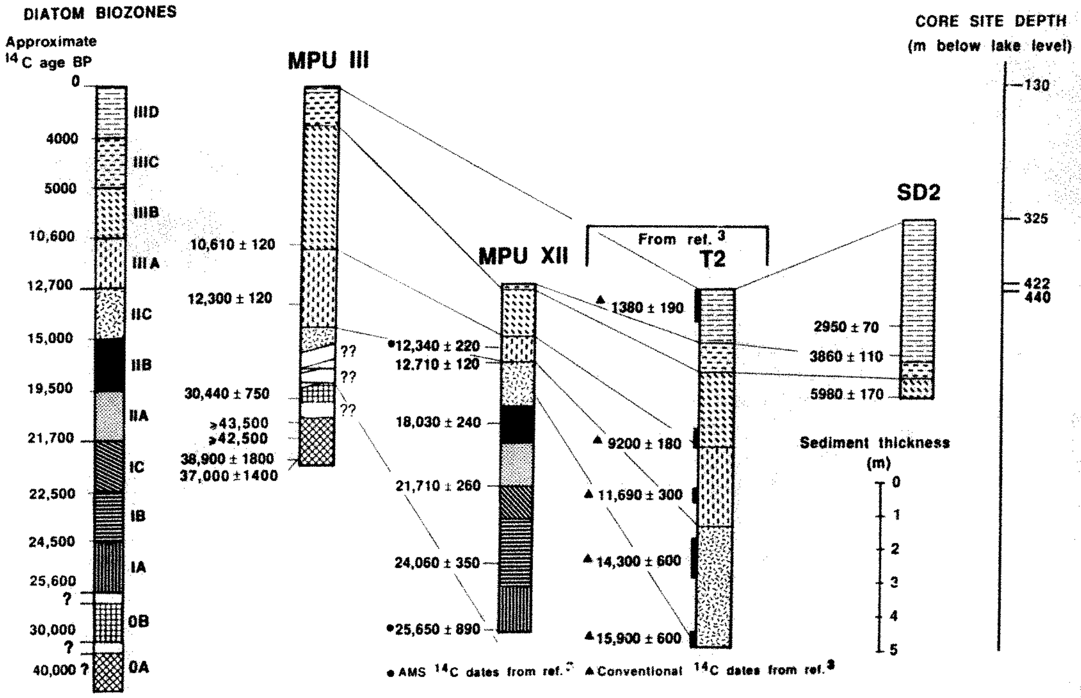

FIG. 4 Tentative correlations between four cores from Lake Tanganyika using diatom biozones. Core T2 from ref. 3. Diatom biozones, abundant taxa: 0 A, *Cyclostephanos* sp. 1; 0 B, *Cyclostephanos damasii*, needle-like *Nitzschia* (*N. spiculum*, *N. nyassensis*, *N. lacustris*; IA: *Cyclotella ocellata*, needle-like *Nitzschia*; IB: *Cyclostephanos* spp. +*Stephanodiscus* spp. needle-like *Nitzschia*, *Cyclotella ocellata*; IC: *Cyclotella ocellata*, *Melosira* spp.; IIA: *Rhopalodia* sp. 1., *Cyclostephanos* spp. +*Stephanodiscus* spp.; IIB: *Gomphonema clevei*, *Rhopalodia* sp. *aff. gracilis*; IIC: *Cyclostephanos* spp. +*Stephanodiscus*, *Surrirella fullebornii*, *Rhopalodia* spp., 2; IIIA: *Cyclostephanos* spp. +*Stephanodiscus* spp., needle-like *Nitzschia*; IIIB: *Melosira* spp.; IIIC: *Cyclostephanos damasii*; IIID: needle-like *Nitzschia*. (needle-like is the terminology used in ref. 3).

the maximum input of organic matter of terrestrial origin and an abrupt increase in rainfall and related runoff which coincides with the limit between biozone IIIA and IIIB.

Below 920 cm, the diatom flora reveals the occurrence of two Late Pleistocene stages of high water level (Fig. 3). The youngest, stage OB, is dated to 30,440 ± 750 yr BP. Facies and diatom flora resemble that of biozone IIIA. The ^{13}C content reflects an almost exclusive aquatic origin of the organic matter. The oldest, stage OA, is characterized by a planktonic diatom assemblage unknown in core MPU XII. Its age falls at or close to the limit of the ^{14}C method (Fig. 3). The slight discrepancies observed between the three measured ages may be due to the presence of detrital organic matter, because the low ^{13}C values indicate an important input of terrestrial material. Such a supply is indistinguishable in the core stratigraphy. An alternative explanation may thus be found in a slight contamination of the 1,108-cm sample which repeatedly provided a still measurable ^{14}C age (Fig. 3).

This survey shows that lake level fluctuations from 26,000 yr BP correlate with changes in global sea level and ice volume[17]: the lake level is intermediate from 26,000 to 21,700 yr BP, is low from 21,700 to 13,000 yr BP with a minimum at 18,000 yr BP and is high from 13,000 yr BP onwards. The reestablishment of a positive water balance occurred during the first step of the deglaciation, but the refilling of the lake is not linear. The abruptness of the major hydrological events recorded at ~13,000 yr BP and ~10,600 yr BP makes the fluctuations of the lake water balance synchronous with the deglaciation steps recorded in the Atlantic ocean[18,19]. Lake Tanganyika fluctuations seem to be in phase with those of the African lakes north of the Equator[20] which are clearly linked to the Milankovitch mechanisms[21]. From the general circulation models we might have expected opposite phases as a result of different insolation values from the astronomical theory of palaeoclimates[22]. Conditions wetter than the present ones, which are predicted by a simulation[23] at 18,000 yr BP in East Africa and attributed to warmer surface temperature of the equatorial Indian Ocean, are not confirmed. More simply, the water balance of Lake Tanganyika reflects the hydrological ocean variations that are due to glaciation/deglaciation processes and the related greater availability of global atmospheric moisture during warmer global climatic phases. ☐

Note added in proof: We have become aware of a related paper[24] which considers the possibility of a time lag of some centuries in the accumulation of organic matter. This hypothesis is based on the isotope balance of C_4/C_3 plants as an index of *in situ* (*Cyperaceae*) versus reworked (trees) organic matter. However, the planktonic contribution, with ^{13}C content lower than for *Cyperaceae*, is neglected, and thus the time-lag estimate is pessimistic.

Glacial–interglacial climatically forced $\delta^{13}C$ variations in sedimentary organic matter

John P. Jasper*‡ & Robert B. Gagosian†

* MIT/WHOI Joint Program in Oceanography, Department of Chemistry, Woods Hole Oceanographic Institution, Woods Hole, Massachusetts 02543, USA

SEDIMENTARY organic geochemical properties have long been used to characterize sedimentary organic matter sources[1–8], but the characterizations are often not unique. There are at least four plausible mechanisms to account for the large (~3–6‰) glacial-to-interglacial climatic variations in the sedimentary organic-carbon isotopic composition ($\delta^{13}C_{org}$) in the northern Gulf of Mexico. They are: temperature-dependent C isotopic fractionation by phytoplankton, mixing of C_3-photosynthetic terrigenous and marine organic matter, mixing of C_3- and C_4-photosynthetic organic matter and diagenetic alteration of the originally sedimented material. In a 208.7-m Deep Sea Drilling Project hydraulic-piston core (DSDP 619) from the Pigmy Basin in the northern Gulf of Mexico, we find that paired analyses of $\delta^{13}C_{org}$ and N/C are consistent with the hypothesis that the sedimentary organic carbon in the Pigmy Basin is a glacial-interglacial climatically determined mixture of C_3-photosynthetic terrigenous and marine organic matter[9], confirming the model of Sackett[5].

The Pigmy Basin is a late Quaternary blocked-canyon intraslope basin the northern Gulf of Mexico[10] (Fig. 1). The basin has normally oxic and saline bottom waters[11]. In interglacial times (isotope (sub)stages 1 and 5a,b) sedimentation rates ranged from 60 to 85 cm kyr^{-1}, whereas during glacial times (isotope stages 2 and 4) sedimentation rates varied from 230 to 250 cm kyr^{-1} as determined from the DSDP Hole 619 hydraulic piston core[9,12]. The occurrence of higher sedimentation rates in glacial stages was presumably due to increased erosion of continental material during falling sea levels and low sea-level stands[13].

We present the sedimentary organic-carbon isotopic composition ($\delta^{13}C_{org}$) of 55 samples from the Pigmy Basin as a time series (Fig. 2*a*). The carbon isotope results are given in the δ-notation relative to the Chicago PDB standard, $\delta^{13}C_{org} = (R_S/R_R - 1) \times 1{,}000$ where R_S and R_R are the $^{13}C/^{12}C$ ratios of sample and reference CO_2 gases[4]. The interglacial oxygen-isotope stages 1 and 5a,b are characterized by relatively positive average ($\pm 1\sigma$) $\delta^{13}C_{org}$ values (stage 1: -24.2 ± 1.2‰, $n = 9$; substages 5a,b: -23.0 ± 0.8‰, $n = 7$), whereas stages 2 and 3 have comparatively negative average values (stage 2: -25.6 ± 0.5‰, $n = 13$; stage 3: -25.2 ± 1.3‰, $n = 18$). Isotope stage 4 has two relatively negative values (average -25.3‰) in the middle of the stage with relatively positive values near the stage 4 boundaries. (3/4 boundary: -22.8‰; 4/5 boundary -21.9‰). To our knowledge this time series is the highest-resolution record of $\delta^{13}C_{org}$ in the Gulf of Mexico spanning from the present interglacial isotope stage 1 to the previous interglacial isotope substage 5b (~96 kyr BP).

Sackett observed a 4.8‰ increase in the carbon isotopic composition of sedimentary organic matter over the last ~20 kyr on the Sigsbee Knolls (core V3-127) in the northern Gulf of Mexico[5]. He attributed the temporal $\delta^{13}C_{org}$ increase to mixing of terrigenous and marine organic carbon sources by analogy with the apparent spatial mixing of terrigenous and marine organic carbon in Recent eastern Gulf Coast surface sediments. The temporal variation of $\delta^{13}C_{org}$ is consistent with a glacial-to-interglacial climatically forced mixing of terrigenous and marine organic carbon[5] and the effects of the ~100-kyr cycle of climatic change[14].

Rogers and Koons[6] examined the $\delta^{13}C_{org}$ records of 24 gravity and piston cores and four 330-m drill cores in the northern Gulf of Mexico, with the longest record extending into the upper Pliocene (~2 Myr). They found that warm stages (as defined by planktonic foraminiferal assemblages) were characterized by $\delta^{13}C_{org}$ values of -20 to -22‰ (relative to PDB), whereas cold stages had $\delta^{13}C_{org}$ values of -24 to -26‰. They eliminated sedimentary diagenesis of organic carbon as a cause for $\delta^{13}C_{org}$ variations because over the time spanned (~2 Myr) there was no secular monotonic trend in $\delta^{13}C_{org}$ values. They concluded that the major cause of the $\delta^{13}C_{org}$ variations was the temperature-dependent fractionation of carbon isotopes by phytoplankton, and considered mixing of terrigenous and marine organic carbon an unlikely cause.

Given the sedimentary $\delta^{13}C_{org}$ variations in the northern Gulf of Mexico, Sackett and Rankin[7] showed that the glacial-to-interglacial sea surface temperature variation predicted from the temperature-induced fractionation of carbon isotopes (35 °C) would be implausibly large in light of the oxygen isotopic composition of contemporaneous planktonic foraminifera[15]. As a temperature change of only 6–10 °C from the last glacial to the present interglacial had been calculated earlier with the $\delta^{18}O$ of planktonic foraminifera in Caribbean surface waters[15], they favoured the variation of relative proportions of terrigenous and marine organic carbon inputs as the cause of the temporal $\delta^{13}C_{org}$ changes. Later, the applications of a foraminiferal-assemblage temperature-transfer method[16,17] and the foraminiferal oxygen-isotope temperature method using revised ice volume estimates[9,18] indicated only small (0.8–2 °C) late Quaternary temperature variations in the northern Gulf of Mexico. These results make temperature-dependent carbon

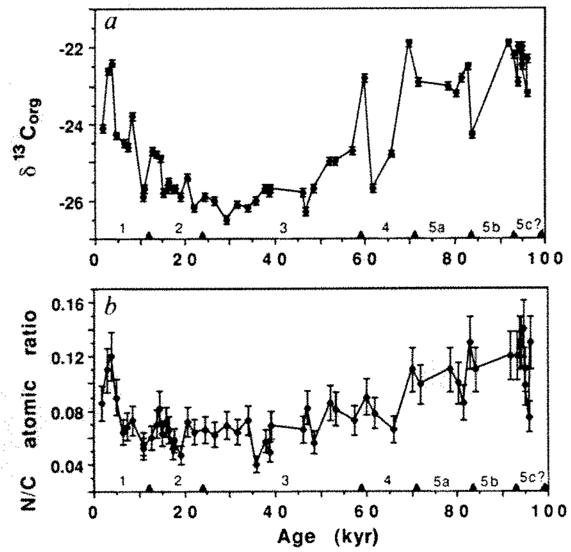

FIG. 2 *a*, Time series of the sedimentary organic-carbon isotopic composition ($\delta^{13}C_{org}$) of DSDP 619 in the Pigmy Basin, showing relatively positive (marine) values in interglacial stages and relatively negative (terrigenous) values in glacial stages. *b*, Time series of N/C atomic ratios in DSDP 619 shows the general interglacial predominance of marine organic matter (typically, N/C = 0.13–0.20) and the glacial predominance of terrigenous organic matter (typically, N/C = 0.01–0.05).

isotopic fractionation an unlikely explanation for the large $\delta^{13}C_{org}$ variations observed in the DSDP 619 core.

Neuman *et al.*[8] observed that the $\delta^{13}C_{org}$ values of "olive grey, Pleistocene turbidite muds" were −22 to −24‰ (relative to PDB) and that the $\delta^{13}C_{org}$ values for "orange and yellow, Holocene and interglacial foraminiferal oozes" were −20 to −16‰. Analysis of the $\delta^{13}C_{org}$ records in 48 piston cores in all the major deep-water provinces of the late Quaternary Gulf of Mexico led them to conclude that the temporal $\delta^{13}C_{org}$ variations were consistent with increased proportions of terrigenous organic-carbon deposition relative to marine organic-carbon deposition in glacial stages over broad expanses of the Gulf's sea floor.

The final alternative is that the sediments of the northern Gulf of Mexico contain a climatically determined mixture of C_3- and C_4-photosynthetic organic matter. Terrigenous C_3-photosynthetic organic matter could be eroded into the Gulf from terrigenous sources in glacial times. In interglacial times, C_4-organic matter could be contributed from C_4-photosynthetic coastal plants[19] or other ^{13}C-rich sea grasses[20] into the deep Gulf of Mexico. We consider this possibility below.

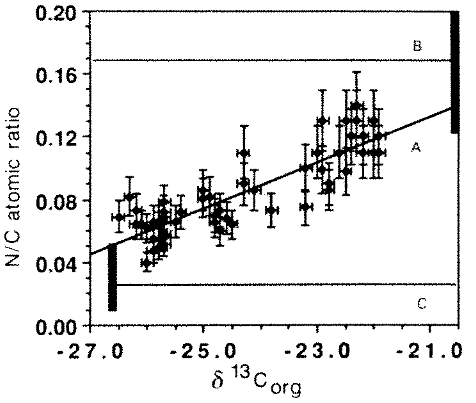
The N/C ratios of DSDP 619 sediments are presented as a time series (Fig. 2*b*). The interglacial (sub)stages 1 and 5a-b are characterized by relatively high N/C values (stage 1: 0.08 ± 0.02 ($\bar{X} \pm 1\sigma$), $n = 9$; substages 5a,b: 0.11 ± 0.02, $n = 7$). These N/C values approach those of planktonic organic matter[1] (0.13–0.20). The average N/C value of glacial stages 2-4 is 0.06 ± 0.02 which overlaps with the range of typical terrigenous plant and peat values of 0.01–0.05 (refs 2, 3). The N/C time series for the Pigmy Basin is consistent with the model of climatically forced glacial-to-interglacial terrigenous- and marine-organic-carbon mixing, reflecting the general ~100 kyr climatic cycle.

In Fig. 3 we plot 55 $\delta^{13}C_{org}$ values against their corresponding N/C values from the Pigmy Basin core. A linear least-squares regression of N/C on $\delta^{13}C_{org}$ shows that the measurements are well correlated ($r^2 = 0.74$, $P < 0.0001$) according to the statistical *F*-test for significance[21]. The correlation of N/C and $\delta^{13}C_{org}$ values for the sedimentary organic matter in the Pigmy Basin is consistent with a mixing of C_3-photosynthetic (Calvin–Benson Cycle of carbon fixation) terrigenous and marine organic matter sources. A linear regression line (labelled A) through the paired data extrapolates through typical terrigenous (0.01–0.05) and marine (0.13–0.20) N/C values at empirically determined $\delta^{13}C_{org}$ terrigenous (−26.6‰, relative to PDB) and marine (−20.6‰) end-member values[9].

These data support the climatically driven terrigenous- and marine-organic-carbon mixture model and are evidence against other hypotheses for organic-matter deposition in the late Quaternary Gulf of Mexico. If temperature-dependent fractionation of carbon isotopes by marine phytoplankton determined the Quaternary sedimentary $\delta^{13}C_{org}$ values, we would expect constant marine N/C values (0.13–0.20) to co-occur with variable $\delta^{13}C_{org}$ values (line B) contrary to observation. This observation is consistent with the assertion that the maximum Quaternary surface-water temperature variation in the Gulf of Mexico would cause only an ~1‰ difference in $\delta^{13}C_{org}$, if it had any effect at all[8]. If a climatically determined mixture of C_3- and C_4- terrigenous organic matter caused the temporal $\delta^{13}C_{org}$ variation, we would observe relatively constant terrigenous N/C values (0.01–0.05) across the range of $\delta^{13}C_{org}$ values (line C). This is also contrary to observation.

Sedimentary organic-carbon isotope results from coastal marshes to Recent deep oceanic environments, showed that there was no convincing evidence for significant diagenetic alteration of the sedimentary $\delta^{13}C_{org}$ records[22]. Although the possibility of diagenetic alteration of Quaternary $\delta^{13}C_{org}$ records has been discussed[6], we are unaware of results that support sedimentary diagenetic carbon isotopic alteration as the cause of large $\delta^{13}C_{org}$ variations (3–6‰) as those observed in the Quaternary Gulf of Mexico sediments[5-9]. Rogers and Koons[6] considered carbon isotopic fractionation during diagenesis to be an insignificant problem affecting the $\delta^{13}C_{org}$ record of 0-2-Myr-old sediments because they did not observe a secular trend in the $\delta^{13}C_{org}$ values. A later study of the $\delta^{13}C_{org}$ of the algal sapropelic sediments of the alternately aquatic, then marine Mangrove Lake in Bermuda, however, indicated an overall decrease in $\delta^{13}C_{org}$ of up to ~4‰ over the past 5 kyr (ref. 23). Therefore, $\delta^{13}C_{org}$ records should not be interpreted solely in

FIG. 3 This plot of N/C against $\delta^{13}C_{org}$ shows that the composition of sedimentary organic matter in the Pigmy Basin (DSDP 619) for the last ~100 kyr is consistent with mixing of terrigenous and marine C_3-photosynthetic (Calvin–Benson Cycle) organic matter. The linear least-squares regression line (A) is: $N/C = 0.015 \cdot (\delta^{13}C_{org}) + 0.44$ ($P < 0.0001$, $r^2 = 0.74$, $n = 55$). For comparison, typical N/C ratios of terrigenous (0.01–0.05) and marine (0.13–0.20) plants are given at $\delta^{13}C_{org}$ terrigenous (−26.6‰) and marine (−20.6‰) endmember values[9]. Constant marine N/C values with variable $\delta^{13}C_{org}$ values (line B) would support temperature-dependent carbon isotopic fractionation as the cause of the late Quaternary Gulf of Mexico $\delta^{13}C_{org}$ variations. Constant terrigenous N/C ratios for all $\delta^{13}C_{org}$ values would support the mixing of C_3- and C_4-terrigenous plant material as the cause of the $\delta^{13}C_{org}$ variations (line C). Neither of the latter two hypotheses (represented by lines B and C) are supported by these data.



terms of organic matter sources, particularly in organic-rich sapropels. In the Mangrove Lake, secularly increasing $\delta^{13}C_{org}$ values were the result of preferential degradation of selected organic-matter components[23]. This mechanism, however, cannot explain the glacial-interglacial cyclic co-variation in $\delta^{13}C_{org}$ and N/C values in the Pigmy Basin. Changes in C_3-photosynthetic terrigenous and marine organic matter sources are supported as the principal source (~74%) of the variation of the $\delta^{13}C_{org}$ and N/C records, whereas sedimentary carbon isotopic fractionation, temperature effects on phytoplanktonic carbon isotopic fractionation and mixing of C_3- and C_4-photosynthetic organic matter may account for some fraction of remaining variation (~26%). These organic-matter source changes are internally consistent with the inverse relations of selected marine (C_{37}–C_{39} alkenones) and terrigenous (C_{27}–C_{29} desmethyl sterols) organic biomarker compounds to $\delta^{13}C$ values also found in the Pigmy Basin sediment core (ref. 9; J.P.J. and R.B.G., manuscript in preparation). □

Sr isotope constraints on the Mediterranean environment at the end of the Messinian salinity crisis

M. T. McCulloch* & P. De Deckker†

* Research School of Earth Sciences, Australian National University, Canberra, Australian Capital Territory, 2601, Australia
† Department of Geology, Australian National University, Canberra, Australian Capital Territory, 2601, Australia

PROBABLY the most profound event that has affected the Mediterranean is the desiccation which occurred at the end of the Miocene[1–8]. During this period, there was a very rapid change from deep, open-marine conditions to environments of shallow-water carbonate and massive evaporite deposition[1–10]. Here we show that ostracod valves found in Messinian Lago Mare (Lake Sea) sediments, have a uniform but generally lower Sr isotopic composition than contemporary sea water thus providing evidence that some of the major Mediterranean basins (for example, Balearic and Levantine basins) formed large lacustrine systems that were probably interconnected towards the end of the Messinian salinity crisis[1–3] after the major evaporites were deposited. The most likely source of fresh water is from continental rivers flowing from the eastern European inland Paratethys sea or perhaps the Nile River. In the lower part of the Lago Mare, some ostracods have Sr isotopic compositions identical to contemporary sea water indicating a transient influence of marine-derived water. Sr compositions greater than that in contemporary sea water are only found in ostracods from onshore sediments in the Sorbas Basin[4,5] of southeastern Spain suggesting that this small basin, adjacent to the Straits of Gibraltar, became isolated after the deposition of the major evaporite sequences.

The events leading up to and during the so-called 'Messinian salinity crisis' have been the subject of diverse interpretations[6–11]. Here we discuss whether the various basins in the Mediterranean were interconnected during the Messinian, the source and quantity of continental drainage flowing into the Mediterranean during that period, whether the Paratethys connection was still open, and whether marine water inundated the Mediterranean at the end of the Messinian salinity crisis, when the Mediterranean consisted of a series of small lakes or a large lake, referred to as Lago Mare[6,8,11].

We assume[12] that the Sr isotopic composition of water masses isolated from the open oceans will, in part, reflect the composition of the continental drainages flowing into the closed basin. As the Sr isotopic composition of sea water is now precisely defined throughout the Tertiary[13–16] it is now possible to resolve even relatively small differences (parts per 10^5) from open-marine environments. In addition, the Sr isotopic composition in all present-day oceans (including the Mediterranean) are identical within analytical errors[13]. With the collision of Eurasia and Africa[17] and the progressive closure of the Tethys Ocean, the Mediterranean became separated from the eastern inland sea, Paratethys, which had previously provided an Indo-Pacific oceanic connection. The Mediterranean's last links to the open-marine environment were probably through the Betic and Rif Straits on the western side (adjacent to the present-day Straits of Gibraltar) which closed in the middle-late Miocene[18]. Thus, with its total isolation, together with the general trend to drier and cooler climate, the Mediterranean was destined for a 'salinity crisis'[1]. We expect this to be reflected in a change of the Sr isotopic composition in the Mediterranean lacustrine system relative to that of the open-marine Messinian sea water.

Ostracods are ubiquitous bivalved microcrustaceans that can live in continental, estuarine, marine and hypersaline waters[19]. Unlike molluscs and foraminifers, which continue to secrete additional layers or chambers, ostracods are arthropods and have to moult and build new valves after shedding the old ones[20]. The components of their low-Mg calcite shells are taken directly from the host water after moulting[21,22] and hence the Sr isotopic composition of the valves is an accurate monitor of the ambient composition of the aquatic environment. The particular ostracod we chose belongs to the well-known euryhaline genus *Cyprideis*. It is cosmopolitan and tolerates a wide range of salinities; modern representative of this genus can be found in fresh waters and in waters with salinities up to 100‰[23]. We analysed ostracods from several Deep-Sea Drilling Program (DSDP) sites (129A, 372 and 376) as well as two onshore sites in Spain and Cyprus. All samples are of Messinian age and postdate the evaporitic depositional phase of gypsum and/or halite, and thus date from very close to the Miocene/Pliocene boundary. We determined the Sr isotopic composition of carefully selected, unaltered single ostracod valves following the procedures outlined in ref. 12. A systematic study of the Sr/Ca ratios in the valves

(Table 1) indicated that diagenetic effects were minimal. We had to analyse single valves because of the extremely limited quantities of material available from the drill-core sites. Here the relevant comparison is with the $^{87}Sr/^{86}Sr$ ratio of sea water of the same date as the Miocene/Pliocene boundary, and hence the results are expressed in ΔSr units which represent deviations in parts per 10^4 from Messinian sea water[24].

The most complete section that has been studied is from DSDP site 376 which is in the Levantine Basin in the eastern Mediterranean. In core 376 the Sr ratios (Table 1 and Fig. 2) are relatively constant for the first 25 m just below the Pliocene/Miocene boundary (core depths of 55–80 m) with ΔSr values ranging from −3.8 to −5.2. In the same depth interval (level 6-4/101, which is equivalent to our sample M16) the controversial 'mystery sapropel' occurs. This consists of reworked giant *Orbulina* specimens together with other planktonic foraminifers and *Cyprideis* ostracods. The nearly constant ΔSr values for samples in this depth interval (55–80 m) is consistent with a sapropel consisting of locally reworked ostracods and foraminifers from slightly older layers. At ~100-m depth (~45 m below the Miocene/Pliocene boundary) the ΔSr values increase to values essentially identical to Messinian sea water ($\Delta Sr \sim 0$). This change in Sr isotopic compositions also coincides with a lithological transition from dolomitic marlstone with sapropelic layers to sandstone with interbedded marlstone. At that particular transition, truly freshwater ostracods (such as *Herpetocypris* and *Metacypris* juveniles, some *Candonopsis* and possibly *Ilyocypris*) were identified together with *Cyprideis*. The presence of these freshwater species excludes the presence of marine water during the lifetime of the ostracods, whereas the Sr isotopic composition indicates host water with a marine ancestry. This dilemma can be resolved by assuming that the ionic components of the early lacustrine water were themselves derived largely from evaporated brines of marine origin and thus obtained a (Miocene) marine Sr isotopic imprint. Alternatively there may have been a transient input of marine water which dominated the Sr isotopic budget for a short period but had little overall effect on the lacustrine environment.

At the base of core 376 (samples M33 and M40) intermediate ΔSr values of −2.8 to −2.5 are found together with Sr/Ca ratios[25] approaching seawater values, whereas at the top of the core, near the Miocene/Pliocene boundary, Sr/Ca ratios lower than contemporaneous sea water are present. Thus, the more negative ΔSr values found in the upper section of the core indicate a trend towards low-salinity continental-derived waters (but still NaCl dominant), whereas the less negative values lower in the section (just above the uppermost gypsum layers) must have been in contact with hypersaline solutions. The presence of marls together with sapropelic layers in the upper section of core 376 (core depth ~50–80 m) also indicates an obvious hydrological transition from salt precipitation in shallow salinas to further dilution by waters with a more obvious continental isotopic imprint.

We have also analysed ostracods from the DSDP core 129A collected in the western Levantine Basin. The ΔSr values fall in the narrow range −4.6 to −5.0 which is the same as that found

Sr isotope ratios were measured on individual valves using techniques described in ref. 12. Measurements were made using a MAT261 with a value for NBS 987 = 0.710200 ± 10.

* True depth in core (from ocean floor).

† Mean Sr/Ca atomic ratios for individual horizons indicating that the ostracod valves did not undergo diagenesis. For further details see ref. 25.

‡ $\Delta Sr = ([^{87}Sr/^{86}Sr_{meas}(t)]/[^{87}Sr/^{86}Sr_{sea\ water}(t)] - 1)10^4$ where $t = 5$ Myr and $^{87}Sr/^{86}Sr_{sea\ water}(t) = 0.708960$ (ref. 24).

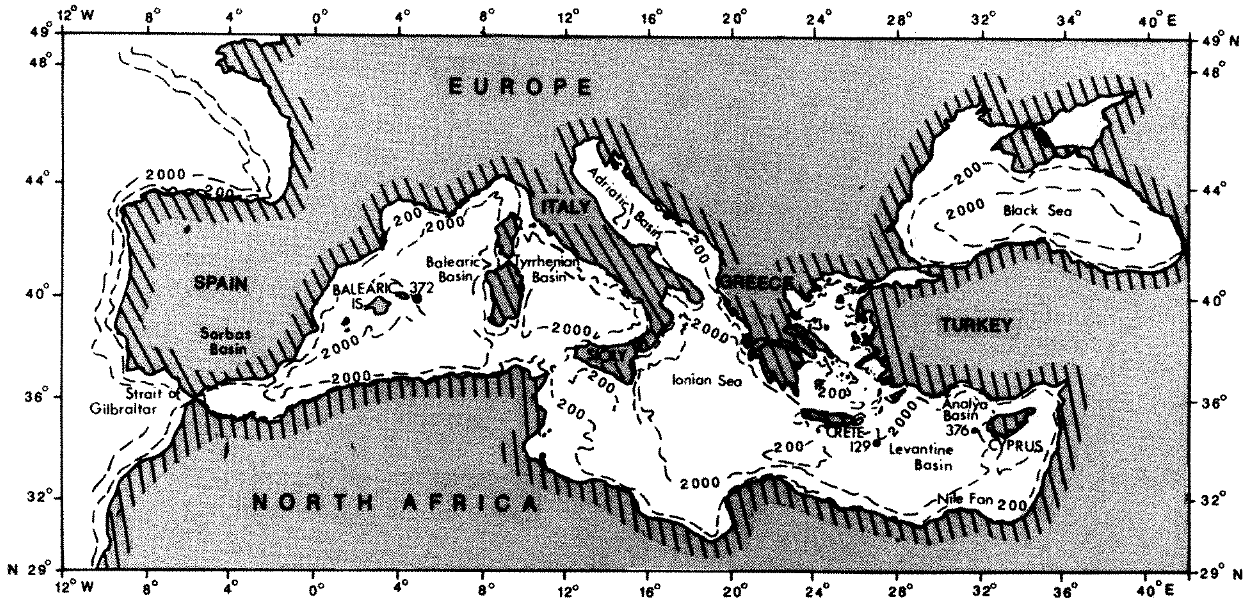

FIG. 1 Map of the Mediterranean Basin showing the location of the DSDP drill holes and the onshore sample sites. Ostracods from the Balearic Basin in the west and the Levantine Basin in the east have similar Sr isotopic compositions indicating the presence of a large (>2,000 km) interconnected lacustrine system.

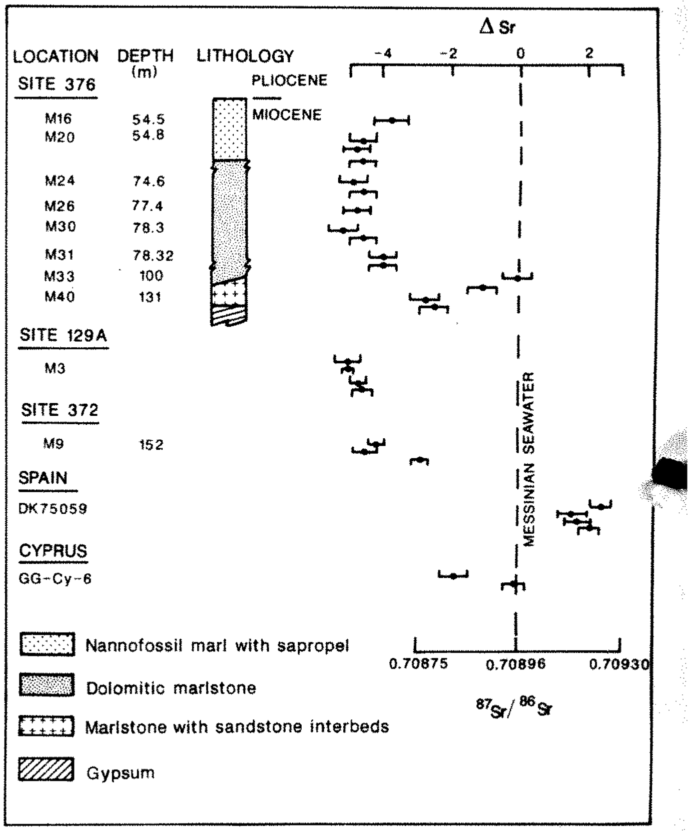

FIG. 2 Graph showing the Sr isotopic composition as a function of depth (in metres below the sea floor) for individual ostracod valves from several DSDP drill-core sites and onshore sites in the Mediterranean basin. The ΔSr values represent deviations in parts per 10^4 of the $^{87}Sr/^{86}Sr$ ratio from the value for Messinian sea water[24].

in the upper 80 m of DSDP site 376 from the same basin. In addition three valves were analysed from DSDP site 372 in the Balearic basin of the western Mediterranean (see Fig. 1). Two of the valves have negative ΔSr values falling within the same narrow range (−4.2 to −4.5) as found in the upper section of sites 376 and 129A from the Levantine Basin. The slightly discordant value of -2.9 ± 0.2 (sample M9C) is identical to that found at the base of core 376. The similar and limited range of negative ΔSr values provides strong evidence for a direct connection between some of the major Messinian, Lago Mare Basins (that is, the Balearic and Levantine Basins), despite the fact that they were separated by distances of over 2,000 km. It is therefore likely that the inland sea, the Paratethys, must have extended as far as the Mediterranean Basin.

The two onshore samples of Messinian age from Cyprus[25,26] also have negative ΔSr values; one value is identical to that Messinian sea water. This is within the same range of values as observed at the base of core 376. In contrast to these results, ostracods from the Messinian of southeastern Spain from the 'white lagoonal limestone' (that is, the white layer which represents the terminal Messinian)[4,5,27] of the Sorbas Basin have positive ΔSr values of 1.5 to 2.4. These values are markedly different from those of the major Lago Mare Basins and clearly imply that the Sorbas Basin had a different continental input compared to the major Mediterranean Basins, including the adjacent Balearic Basin. The distinctive ΔSr values indicate, contrary to what is observed in the other Messinian Mediterranean basins, that the Sorbas Basin was a restricted (barred) basin isolated from the rest of the Mediterranean after deposition of the gypsum evaporitic beds. The Sr/Ca ratios in ostracods from the Sorbas Basin form a broad range; some of the values are different from typical Messinian marine waters. This further confirms the independent conclusion[27] based on the Zorreras Member from the Sorbas Basin (within which the white lagoonal limestone occurs) which was deposited at the time of closure of the Betic Straits.

Our results for sites 376 and 129A in the Levantine Basin, site 372 from the Balearic Basin and the onshore samples from Spain and Cyprus, have a number of important implications for the palaeoenvironment of the Messinian Mediterranean. The exceedingly narrow range of negative ΔSr values provides good evidence for a direct connection between the widely separated large basins of the Lago Mare in the Mediterranean, immediately before the Pliocene transgression. The Sorbas Basin on the western edge of the Mediterranean seems to be an exception. These observations are consistent with the deep-basin model[1-4,28] of the Messinian Mediterranean, in which a large 'inland sea' (the Lago Mare[6,8,11]) formed that was largely isolated from the open-marine environment at the end of the Messinian. Thus the 'wet' Mediterranean theory[29] may have some relevance for the Lago Mare phase, but it is clear that a lacustrine, not a marine, environment existed. A lacustrine environment close to freshwater is indicated by the Mg/Ca ratios *Cyprideis* ostracods[25] as well as by the presence of truly freshwater ostracod taxa.

The obvious lithological change from sandstones to marls with sapropelic layers coinciding with low Sr/Ca ratios (Table 1) and a change in ΔSr values of the ostracod shells, indicates an influx of fresh (or brackish) continental water at site 376. It has been proposed[1] that the source of this water is the inland Paratethys Sea of eastern Europe. To account for the negative ΔSr values the inflowing waters must also have ΔSr values as, or more negative, than those observed. This could be the result of dissolution of Sr from young volcanic provinces or, more probably, from older limestones. From the Sr-isotope seawater curve[13-15], lower Tertiary or limestones as old as Ordovician would be suitable sources. Another possible source is the Nile River. At present the Nile has a very negative ΔSr value ($\Delta\text{Sr} \sim -60$)[30,31] and its waters could rapidly lower the Sr isotopic composition of the Mediterranean Lago Mare lacustrine waters. The narrow range of only slightly negative ΔSr values that has been observed for the widely separated sites, 376 and 372, however, suggests that it is unlikely that Nile River water was a significant input to the Mediterranean Basin. The seawater-like ΔSr values at the bottom of core 376 and in the Cyprus sample, together with the presence of ostracods of lacustrine affinity, may be due to a transient marine influx but is more probably due to redissolved, evaporated brines containing Sr that had a marine origin. Throughout this period (latest Messinian) the ostracods indicate that the waters in the Lago Mare remained NaCl-dominant (that is, chemical pathway II [32]), even in their dilute stage, as shown by the presence of *Cyprideis* ostracods which have a preference for this type of water[33]. □

Hydrothermal oil of Guaymas Basin and implications for petroleum formation mechanisms

Borys M. Didyk* & Bernd R. T. Simoneit†

PETROLEUM-LIKE hydrocarbons have been detected in thermally altered Recent sediments of Guaymas Basin[1-5] and petroleum-like hydrocarbon impregnations were found in hydrothermal mounds on the sea floor and associated with hydrothermal vent emissions[5-9]. Here we report the evaluation of such a hydrothermal oil, which we find to be similar to conventionally exploited crude oils. Its young geological age (<5,000 yr, ^{14}C)[10] indicates that a significant fraction of the organic carbon in the oil has completed the transformation from biomass to migrating oil in less than 5,000 years, thus limiting the oil generation, explusion and migration processes to a geologically short timescale. We estimate the generation potential of such hydrothermal oil and discuss its implications to our understanding of the petroleum generation, expulsion and migration mechanisms.

Guaymas Basin, located in the central part of the Gulf of California, is part of a rift zone that links the East Pacific Rise in the south with the San Andreas Fault leading north. The tectonic graben-like basin is covered by thick layers of sediments (up to ~500 m), consisting of diatomaceous ooze and terrigenous silty mud[11,12]. Hydrothermal activity in the area was postulated on the basis of anomalously high heat flow[11,13,14] and then detected by instrument-assisted observations[15]. Later, diving with the submersible *Alvin* allowed direct sampling and gathering of visual evidence on the hydrothermal systems of Guaymas Basin[16-18].

The hydrothermal activity in Guaymas Basin releases[17,19-21] discrete oil globules (up to 1-2 cm in diameter), which are discharged into the water column with the hydrothermal fluids. The disturbance of the surface layers of bottom sediments and chimney debris also releases oil globules. Direct measurement of the oil flow rate at the vent sites has so far not been feasible, but the *in situ* collection of oil globules showed that the gas/oil ratio is ~5, with possible gas dissolution in hydrothermal water and seawater exposure of the oil before and during expulsion from the vent system[22]. Low bottom temperatures (2-3 °C) contribute to condensation and retention of some of the oil and this generates oil impregnations on and in inorganic substrates of the hydrothermal vent systems.

A hydrothermal chimney (40-cm length × 8-12 cm diameter; ~1,500 g), was removed from a vent that was releasing hydrothermal fluids (translucent water, at ~200 °C) at the moment of sampling (DSV *Alvin* Dive 1630, Fig. 1 insert) at 2,020-m water depth[20,22]. At the surface the sample was sealed in double, pre-washed Kapak bags and frozen (−40 °C) until analysis.

The hydrothermal chimney consisted of a porous unconsolidated inorganic matrix (57.0%), water (19.2%) and a high organic matter content (23.8%). On thawing the sample released 2.1% of free-flowing oil. The vapour phase in contact with the sample was analysed for light hydrocarbons and alkanes from methane (15.5%) to hexadecane (0.7%) were detected. Selected hydrocarbon ratios[22] are similar to those of the gasoline fraction of typical crude oils. The general distribution pattern of light volatile hydrocarbons in this chimney resembles that of crude oils, with the exception of a lower content of aromatic hydrocarbons. This is probably caused by water washing and results from the sample-water contact during formation of the chimney, sample collection and retrieval from the sea floor (~2,000-m depth). No olefins were detected among the volatile hydrocarbons indicating that the organic matter had not been exposed to severe thermal cracking processes. The inorganic matrix of the chimney consisted predominantly (85%) of barium sulfate crystals[23], with the organic matter adsorbed and impregnating the interstitial pore space of the unconsolidated barite matrix.

The hydrothermal oil from the Guaymas Basin is similar to reservoir crude oils. First, the total extractable organic matter distilled over the normal range, but the gasoline fraction is low indicating that a significant portion of the volatile (C_1–C_{10}) components were lost in the thermocline before recovery and preservation. Second, the elemental composition (Table 1*a*) is within the normal ranges of typical crude oils[24], with slightly higher contents of vanadium and nickel as we expect for a light oil with a relatively high content of intermediate distillation products. Third, the porphyrin and biomarker contents and their distribution in this sample are well within the range of normal crude oils[25], indicating moderate degrees of maturation and thermal stress. Fourth, the compound-class composition (Table 1*a*) is just like a typical reservoir crude.

* >200 °C fraction of oil.

† ETIO, etioporphyrins.

‡ DPEP, deoxophylloerythroetioporphyrins.

§ Conversion of DPEP to ETIO porphyrins is associated with the thermal evolution of geolipids[31] and is also associated with a decrease in porphyrin concentration and displacement of the porphyrin-carbon-number maximum towards lower values[32].

‖ Other biomarkers in the hydrocarbon fraction consist of triterpenoids, extended tricyclic terpanes and steranes with their rearranged analogues (diasteranes)[6,8,9,33]. Minor extended tricyclic terpanes range from C_{20} to C_{29} with a similar distribution pattern as observed for other mature petroleum samples. The triterpanes are essentially 'mature' in their more stable configurations and are comprised primarily of the 17α(H), 21β(H)-hopane series ranging from C_{27} (no C_{28}) to C_{35}, with the homologues from C_{31}–C_{35} present as 22-*S* and *R* epimer pairs in a ratio of about 1.3 (*S*/*R*)[6,8]. Minor amounts of 17β(H), 21α(H)-hopanes (moretanes, C_{29}, C_{30} and C_{31}) are also present.

¶ The steroidal markers primarily consist of 5α(H), 14α(H), -17α(H)-steranes (20*R*), and diasteranes mainly as the 13β(H), 17α(H)-20 *R* or *S* series. The steranes range from C_{26} to C_{30}, with cholestane as the major homologue. The distribution pattern indicates a marine autochthonous origin, an intermediate maturity and is comparable with data for other samples from the area[6,8].

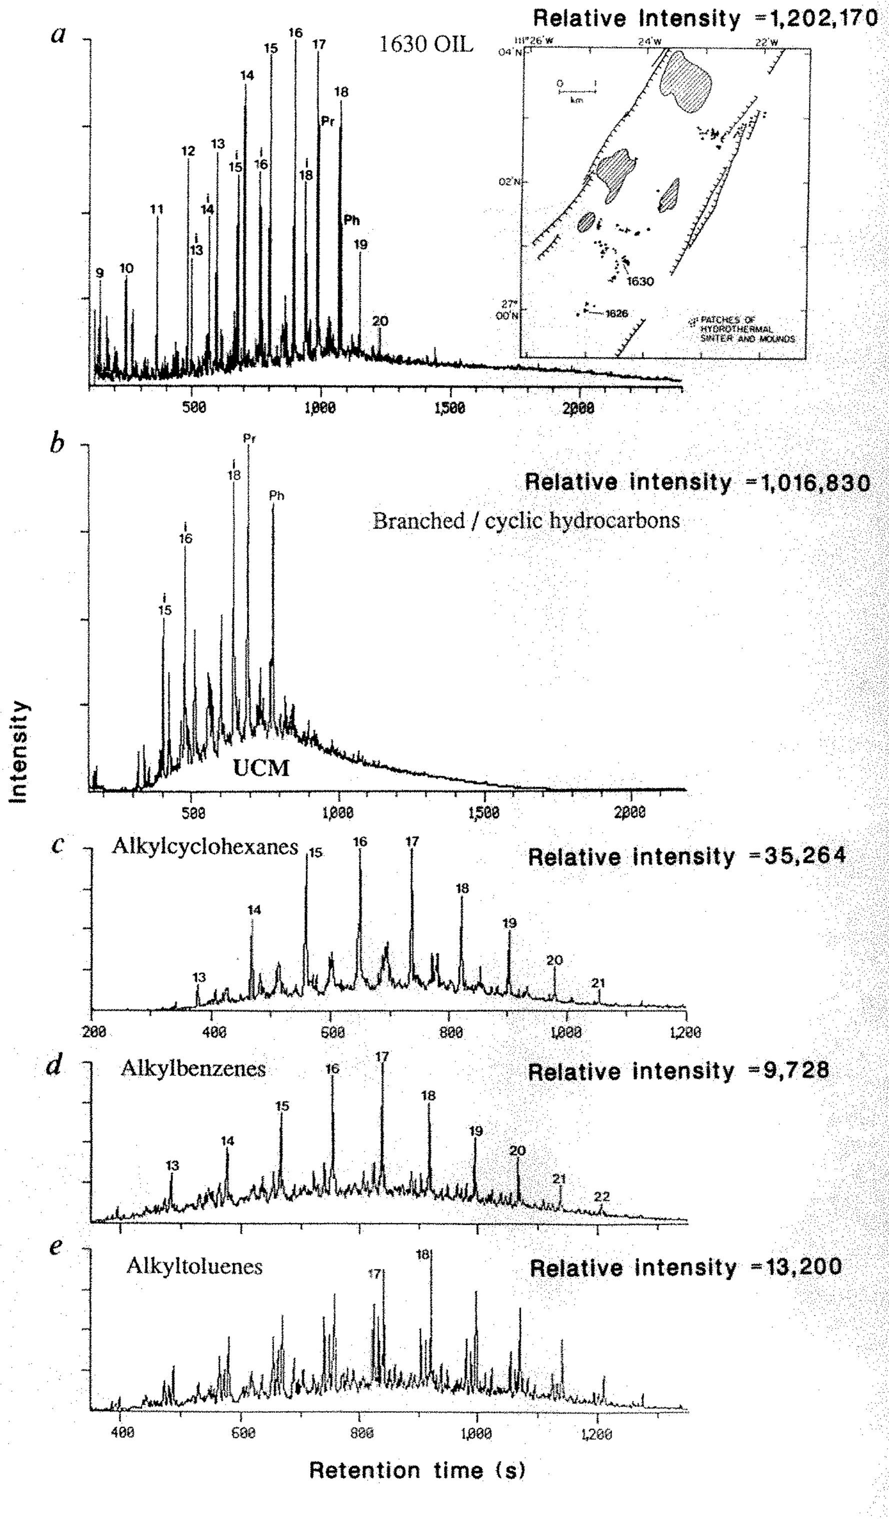

FIG. 1 Salient features of the gas chromatography/mass spectrometry data for the *a*, total and the *b*–*e*, branched-cyclic hydrocarbons of oil sample 1630 (inset in *a* location map of the dive area in the south rift of Guaymas Basin). *a*, Total ion-current trace (numbers refer to *n*-alkanes, i *n* to isoprenoid hydrocarbons, Pr to pristane, Ph to phytane). The *n*-alkane range for the stabilized oil (C_{12}–C_{24}, max C_{15}) has a monomodal, narrow carbon-number distribution with no carbon preference (carbon preference index C_{12}–C_{22}=0.99), compatible with a predominantly bacterial/algal origin for the source organic matter and with an adequate degree of maturation. *b*, Total ion-current trace (i *n*, isoprenoid hydrocarbons; UCM, unresolved complex mixture, that is, naphthenes). A range of isoprenoid hydrocarbon biomarkers is present, C_{15}–C_{20} (no C_{17}) and pristane as the dominant homologue. *c*, $m/z=83$, key ion for alkylcyclohexanes (numbers indicate carbon number of homologues). *d*, $m/z=91$, key ion for alkylbenzenes. *e*, $m/z=105$, key ion for alkyltoluenes. On the whole, these distributions are compatible with an algal/bacterial origin for the organic matter.

The gas chromatography/mass spectrometry data (Fig. 1) are compatible with a predominantly bacterial/algal origin for the source organic matter and suggest an adequate degree of maturation.

Sediments have been accumulating in the rift areas of Guaymas Basin for ~150,000 yr at an assumed rate of 0.2 cm yr^{-1} and this, combined with turbidite flows, has resulted in a ~400-m layer of diatomaceous ooze[11]. Thus, if the oil associated with these vent systems has not originated outside the rift areas and is, as indicated by previous geological and geochemical evidence[11,17], autochthonous from the Guaymas Basin sediments, it has probably formed by the action of hydrothermal processes on the organic matter of these relatively Recent sediments[4,5,7]. Radioactive-carbon isotope (^{14}C) dating of the oil from this and a nearby area (dives 1630 and 1626) gives ages of 4.2-4.9 × 10^3 yr with uncertainties in the range 50-190 yr (ref. 10). Therefore, in Guaymas Basin, the overall time-temperature conversion of sedimentary organic matter to hydrothermal petroleum takes place over a short geological timescale (<5,000 yr) and commences under relatively mild temperature conditions, as indicated by the presence and characteristics of the biomarkers. The oil expulsion and migration mechanisms are provided by the hydrothermal fluids under pressures of 200 bars and temperature conditions up to and exceeding 315 °C

FIG. 2 Schematic models for hydrothermal petroleum generation and migration scenarios: *a*, Guaymas Basin open system (in excess of ~200 bar). *b*, Hypothetical closed system.

at some vent outlets. There are probably near-critical conditions further down in the sedimentary column[8,26,27].

The hydrothermal petroleum is discharged into the water column, where it is exposed to water washing, dispersion and active biodegradation. This is supported by the compositional data for petroleum impregnations with different degrees of environmental exposure and biodegradation in the Guaymas Basin area[6-8]. Thus, hydrothermal-oil transport and release results in its dispersion, alteration and eventual loss. A schematic representation of the prevailing conditions in the Guaymas Basin systems[28] is shown in Fig. 2*a*. Hydrothermal fluids driven by a deep heat source, permeate through an open, fine-grained body of Recent sediments and discharge directly into the water column. The oil discharged with the hydrothermal fluids partially adsorbs or condenses on inorganic substrates cooled by sea water (~3 °C) surrounding the vents. The major part of the oil plume above the vent area dissipates into the water column mainly by dispersion, dissolution and eventual biodegradation. Another scenario could be postulated (for example, Fig. 2*b*) where a similar hydrothermally generated oil is discharged into a porous sedimentary body, with a finite retention time for the fluids. There the hydrothermal oil-water mixtures can undergo phase separation and petroleum could eventually accumulate if adequate sedimentary and tectonic features are available.

TABLE 2 Hydrothermal petroleum potential of Guaymas Basin (South Trough)

Basic considerations used for estimate:	
Area of hydrothermal activity presently known	~3 × 10 km = 30 km^2
Sedimentary layer	~300–500 m* = 400 m
Hydrothermally altered sedimentary layer	lower 120 m* = 120 m
Porosity	40–80%* = 50%
Organic carbon (dry weight, unaltered section)	av. 2%† = 2%
Organic carbon (altered section)	decreases to 0.2%† = 0.2%
Estimates:	
Sediment volume (dry basis)	= 2 × 10^8 m^3 km^{-2}
Sediment weight (dry, used density 1 g cm^{-3})	= 2 × 10^8 t km^{-2}
Organic carbon converted (2% to 0.2% = 1.8%)	= 1.08 × 10^6 t OC km^{-2}
Organic matter (oil = 85% TOC)	= 1.3 × 10^6 t oil km^{-2}
Total oil in altered section of area (30 km^2)	= 40 × 10^6 t

* Compare to data in ref. 11.
† Compare to data in ref. 32.

In Guaymas Basin the presently known area where hydrothermal activity reaches the sea floor is ~3 × 10 km and the lower 120-m section of the sediments drilled was hydrothermally altered[11]. An average porosity of ~50% and an organic carbon decrease from 2.0 to 0.2% (typical of the area[29]) give a value for total organic matter (oil potential) susceptible to hydrothermal alteration and fluid leaching of the order of 1.3 × 10^6 t km^{-2} of alteration zone (Table 2). This gives a maximum organic-matter availability of ~40 × 10^6 t for the presently known hydrothermally active area of the basin (Table 2). So far no data is available on the ultimate efficiency of hydrothermal petroleum generation processes prevailing in Guaymas Basin. The combination of field data with a conservative potential-yield calculation, however, indicate a high efficiency and significant quantities of hydrothermal oil could have been generated by this relatively small area during its geologically active lifetime. If larger areas and volumes of sediments were involved (where there is, at present, no evidence that hydrothermal activity reaches the sea bottom or if larger hydrothermally altered areas have formed because of hot-spot displacement along the tectonic axis of the graben during its geologic evolution) the overall hydrothermal-petroleum generating potential of the area could be considerably larger.

The generally accepted model of oil generation, postulated to be responsible for the formation of the major part of the presently exploited petroleum, assumes long-term maturation of sedimentary organic matter in subsiding sedimentary basins, where the organic matter undergoes successive and gradual increases in geothermal alteration leading to a process of continuous oil generation. The expulsion of the oil and its subsequent migration occur later and only after the geothermal maturation of the original organic matter. This multistep oil formation process has a low efficiency and converts only a minor fraction of the original organic matter of the sediment to oil. There is also difficulty in balancing and timing an adequate degree of geothermal maturation (oil generation) occurring at intermediate stages of basin evolution and ample fluid availability (expulsion), with the retention of sufficient intergrain porosity for adequate fluid transport (migration).

Although considerable progress in the understanding of this multistep oil formation mechanism has been achieved, there are still problems that need to be solved[30]. Such a slow multistep mechanism differs significantly from hydrothermal petroleum formation, which can be geologically fast (here 5,000 yr) indicating a single-step mechanism in which generation occurs almost concurrently with expulsion and migration. In addition the whole hydrothermal process can take place during the early stages in the geological history of a basin.

Although hydrothermal oil formation has been detected, identified and documented, no evidence is so far available on the extent to which this alternative single-step oil generation process has contributed towards the origin of presently exploited oil reserves. As no hydrothermal-oil reservoirs have yet been identified, a trapping mechanism is not known, but could proceed according to the scenario described in Fig. 2*b*. Nevertheless, hydrothermal oil generation occurs and could result in oil accumulations under favourable geological constraints. Hydrothermal oil formation provides an efficient single-step mechanism for petroleum generation, expulsion and migration which could have a considerable impact on our understanding of petroleum formation mechanisms and eventually assist us in tapping resources in new areas. ☐

THE contribution of anoxygenic photosynthesis to carbon cycling in the Black Sea, the world's largest body of anoxic marine water, has been vigorously investigated and debated for over four decades[1–6]. Penetration of light into the sulphide-containing deep water may result in a zone of anaerobic primary production by photosynthetic bacteria. We report here the results of analyses of photosynthetic pigments in samples of suspended particulate matter collected from two stations in the western basin of the Black Sea. Our data demonstrate high concentrations of a bacteriochlorophyll at the chemocline, and thus the potential for anoxygenic photosynthesis as a component of primary production in the carbon cycle of the Black Sea[6]. More than 95% of the pigments in the bacteriochlorophyll-maximum are accounted for by a series of aromatic carotenoids and bacteriochlorophylls-*e*, including a previously unreported geranyl ester of 4-*i*-butyl bacteriochlorophyll-*e*. The distribution of pigments is characteristic of the obligate phototrophs *Chlorobium phaeobacteroides* and *C. phaeovibriodes*. Total depth-integrated bacteriochlorophyll at one station exceeded total chlorophyll-*a* in the overlying oxygenated portion of the euphotic zone. We suggest that anoxygenic photosynthesis is a relatively recent phenomenon in the Black Sea initiated by shallowing of the chemocline over the past decade and development of an anoxic layer devoid of O_2 and H_2S (ref. 7).

Suspended particulate matter was collected on RV *Knorr* cruise 134, leg 9 (Instanbul to Istanbul, Turkey) in May 1988. Station BS2-1 (42°10′N, 30°00′E) is located 110 km from the Turkish coast in 2,110 m of water, and is most heavily influenced by terrigenous material advected from the shelf-slope region of the adjoining coast. Dissolved oxygen was maximal (320 μM, 5% supersaturation) at 20 m and rapidly decreased to <2 μM (limit of detection) at depths >80 m. Dissolved sulphide was detected in all the samples that were collected below 100 m. Station BS2-2 (42°50′N, 32°00′E) is located in the centre of the western basin and is characterized by a shallower chemocline. Dissolved oxygen decreased from a maximum of 307 μM at 20 m to <2 μM at >56 m. Sulphide was detected at depths as shallow as 80 m (Fig. 1). The distributions of photosynthetic pigments in the oxic portion of the water columns at each station were similar (Table 1). The major pigments included: chlorophyll-*a*, chlorophyll-c_1 and chlorophyll-c_2, which are widely distributed in marine algae; chlorophyll-c_3, 19′-butanoylfucoxanthin and 19′-hexanoylfucoxanthin, which are characteristic of prymneseophytes[8,9]; and fucoxanthin, which is widely distributed but characteristic of algae from the class Bacillariophycae[10] (Fig. 2).

Particulate matter samples collected from 90–121 m (station BS2-1) and 60–110 m (station BS2-2) all contained abundant bacteriochlorophylls and bacteriocarotenoids. Four components were isolated that had visible absorption maxima in acetone of 463 and 653 nm. The main component (45% of the total) and two lesser components (16 and 15% of the total) were identified, respectively, as the 4-ethyl, 4-*n*-propyl and 4-*i*-butyl (Fisher nomenclature) homologues of bacteriochlorophyll-*e* by mass spectrometry and comparison of chromatographic retention

Concentrations are those in suspended particulate matter samples from two stations in the Black Sea. Compound designations are as follows: Fxn, fucoxanthin; 19'-HFxn, 19'-hexanoylfucoxanthin; Chl-*a*, chlorophyll-*a*; GBChl, bacteriochlorophyll-*e* geranyl ester; EBChl, 4-ethyl bacteriochlorophyll-*e*; PBChl, 4-*n*-propyl-bacteriochlorphyll-*e*, BBChl, 4-*i*-butyl-bacteriochlorophyll-*e*; IR, isorenieratene; β-IR, β-isorenieratene. Blank spaces denote nondetectable (<1 ng l^{-1}) pigments.

times (HPLC) with authentic standards. The fourth component (23% of the total) did not elute with any known bacteriochlorophyll-*e*. The chromatographic and spectroscopic properties of the compound initially indicated that the compound was a diastereomer or the 4-ethyl, 5-methyl homologue of bacteriochlorophyll-*e*. Diasteromers of bacteriochlorophyll-*e* have been isolated from two strains of (cultured) *Chlorobium phaeovibrioides*[11], but separation of these diastereomers by using a reverse-phase HPLC system similar to the one used here was not achieved, and it seemed unlikely that the modifications to our chromatographic analyses would have achieved such a separation. The chemical ionization (methane) mass spectrum of the pure bacteriophaeopigment that was derived from the unidentified component displayed a molecular ion at $m/z = 758$ (M+1) with major fragment ions at $m/z = 740$ (M+1−water), 622 and 604 (Fig. 3). Major fragment ions at $m/z = 622$ (macrocyle) and 604 (macrocycle-water) were also present in the mass spectrum of 4-*i*-butyl-bacteriophaeofarnesyl-*e* (derived from 4-*i*-butyl-bacteriochlorophyll-*e*). The two compounds share a common macrocycle, but differ in the esterifying alcohol. Other bacteria of chlorobiaceae are known to produce bacteriochlorophyll-*c* and -*d* with a suite of esterifying alcohols. Only the farnesyl ester of bacteriochlorophyll-*e*, however, has been reported. The mass difference of 68 AMU between the molecular ions of 4-*i*-butyl-bacteriochlorophyll-*e* and the new bacteriochlorophyll in our sample corresponds to a difference of C_5H_8 (isoprene) in the esterifying alcohol. Therefore, we tentatively identify the new bacteriochlorophyll-*e* in our samples as the geranyl ester of 4-*i*-butyl-bacteriochlorophyll-*e*. It is interesting to note that, although the ethyl, *n*-propyl, and *i*-butyl homologues of bacteriochlorophyll-*e* occurred in nearly constant proportions in all our samples (irrespective of depth or station location), only the *i*-butyl homologue of geranyl-bacteriochlorophyll-*e* was detected.

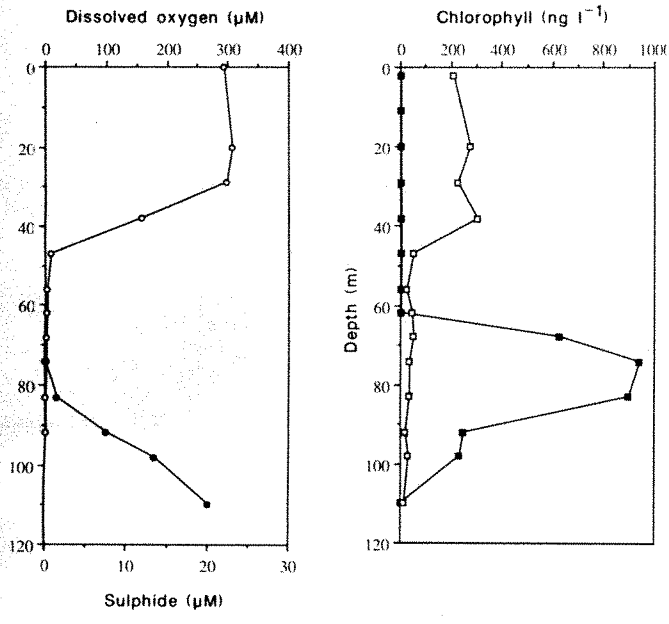

FIG. 1 The distribution of chlorophyll-*a* (□), total bacteriochlorophyll-*e* (■), dissolved oxygen (○), and hydrogen sulphide (●) at station 2 on 17 May 1988.

Concentrations of total bacteriochlorophyll-*e* reach a maximum of 214 ng l^{-1} at 100 m (station BS2-1) and 940 ng l^{-1} at 74 nm (station BS2-2) (Table 1). The lower concentration of bacteriochlorophyll-*e* at station BS2-1 is associated with a deeper chemocline and a lower ambient light intensity. From the relative distribution of pigments at the two stations, bacterial growth seems to be limited by penetration of light into the sulphide-containing deep water. A 0.1%-light-level depth of

Hashwa and Trüper[5] did not find viable photosynthetic bacteria in Black Sea water sampled in and below the chemocline, which was then at a depth of 140 m. Isolates of photosynthetic bacteria from sediment (collected at 2,000 m) were attributed to survival as chemo-organotrophs on dissolved organic matter. Our results signify that at the H_2S interface depth of 80–100 m that exists now, anaerobic photosynthesis has become a singificant process in the Black Sea carbon cycle. The shallowing of the chemocline was accompanied by the separation of the oxygenated upper layer and the shallowest appearance of H_2S by a suboxic layer ($<5\ \mu M\ O_2$) of 20–30 m (Fig. 1). Considerations of possible electron acceptors for anaerobic H_2S oxidation support the phototrophic reduction of CO_2 to organic carbon. Thus, the Black Sea supports the largest and deepest extant community of anoxygenic photosynthetic bacteria in the world, and may serve as a suitable model for studies of carbon recyling in the suboxic and anoxic seas of Cambrian and Precambian times. ☐

MANY cellular functions are regulated by activation of cell-surface receptors that mobilize calcium from internal stores sensitive to inositol 1,4,5-trisphosphate (Ins(1,4,5)P_3) (ref. 1). The nature of these internal calcium stores and their localization in cells is not clear and has been a subject of debate. It was originally suggested[2–5] that the Ins(1,4,5)P_3-sensitive store is the endoplasmic reticulum, but a new organelle, the calciosome, identified by its possession of the calcium-binding protein, calsequestrin[6], and a Ca^{2+}-ATPase-like protein[7] of relative molecular mass 100,000 (100K), has been described as a potential Ins(1,4,5)P_3-sensitive calcium store. Direct evidence on whether the calciosome is the Ins(1,4,5)P_3-sensitive store is lacking. Using monoclonal antibodies raised against the Ca^{2+}-ATPase of skeletal muscle sarcoplasmic reticulum[8], we show that bovine adrenal chromaffin cells contain two Ca^{2+}-ATPase-like proteins with distinct subcellular distributions. A 100K Ca^{2+}-ATPase-like protein is diffusely distributed, whereas a 140K Ca^{2+}-ATPase-like protein is restricted to a region in close proximity to the nucleus. In addition, Ins(1,4,5)P_3-generating agonists result in a highly localized rise in cytosolic calcium concentration ($[Ca^{2+}]_i$) initiated in a region close to the nucleus, whereas caffeine results in a rise in $[Ca^{2+}]_i$ throughout the cytoplasm. Our results indicate that chromaffin cells possess two calcium stores with distinct Ca^{2+}-ATPases and that the organelle with the 100K Ca^{2+}-ATPase is not the Ins(1,4,5)P_3-sensitive store.

Three monoclonal antibodies raised against the Ca^{2+}-ATPase of skeletal muscle sarcoplasmic reticulum[8] were used to identify the distribution of putative calcium stores in adrenal chromaffin cells. The antibodies fortuitously had different reactivities with chromaffin cell polypeptides. In chromaffin cells (Fig. 1), monoclonal antibody 1/2H7 recognized a polypeptide of relative molecular mass 140K, whereas monoclonal Y/1F4 recognized a distinct polypeptide of relative molecular mass 100K. Monoclonal antibody B/3D6 was used as a control as it did not recognize any chromaffin cell polypeptides in immunoblotting

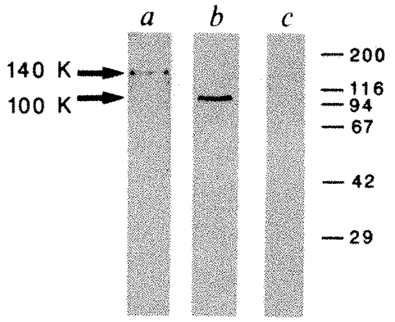

FIG. 1 Characterization of polypeptides recognized by monoclonal antibodies against skeletal muscle Ca^{2+}-ATPase in adrenal chromaffin cells. After SDS-PAGE, polypeptides recognized by the antibodies were determined by immunoblotting with *a*, 1/2H7; *b*, Y/1F4; and *c*, B/3D6. On the right are indicated the migration positions of molecular weight standards (in thousands).

METHODS. Chromaffin cells were dissociated from bovine adrenal medulla and grown in 24-well trays at a density of 7×10^5 cells per well as described previously[10]. After 24 h in culture the cells were solubilized in 150 µl of SDS-solubilization buffer[25] and polypeptides separated by SDS-PAGE on 10% slab gels. After transfer of proteins to nitrocellulose by transverse electrophoresis, the blots were stained with Ponceau S, washed with PBS medium and incubated with 3% non-fat skimmed milk in PBS for 30 min, followed by incubation for 60 min with the monoclonal antibodies diluted (1:250 for 1/2H7, 1:100 for Y/1F4 and 1:250 for B/3D6) in PBS. The blots were then incubated sequentially with anti-mouse biotin (Amersham; diluted 1:100) for 60 min and horseradish peroxidase-streptavidin (Amersham; diluted 1:500) for 30 min in 3% non-fat skimmed milk, 0.5% Tween 20 in PBS, and the reaction developed with diaminobenzidine hydrochloride/H_2O_2.

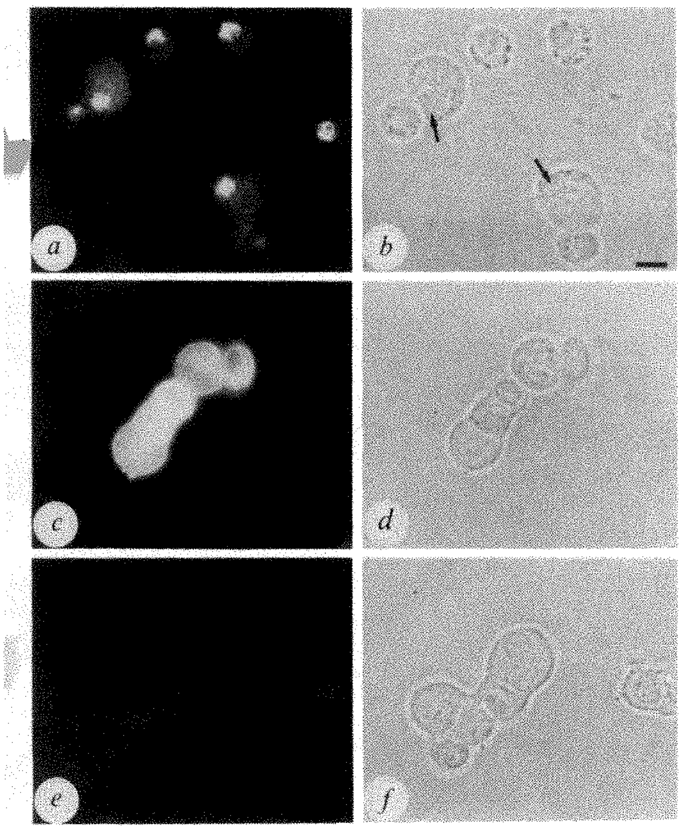

FIG. 2 Immunofluorescence localization of Ca^{2+}-ATPase-like proteins in adrenal chromaffin cells. Chromaffin cells were stained with 1/2H7 (*a, b*), Y/1F4 (*c, d*) or B/3D6 (*e, f*). Fluorescence images are shown in *a, c, e* and corresponding phase-contrast images in *b, d, f*. Antibody 1/2H7 gives a localized staining pattern restricted to a region over the nucleus of the cells. In some cases the whole of the nucleus is not stained, it being restricted to a region at the back. By contrast, Y/1F4 gives a diffuse staining pattern over the whole cell and B/3D6 does not stain the cells. Scale bar in *b*, 10 μm.

METHODS. Adrenal chromaffin cells were grown in culture overnight on glass coverslips and fixed in 4% formaldehyde. The cells were washed in PBS and incubated in 0.3% BSA, 0.1% Triton X-100 in PBS (PBT) for 30 min, followed by incubation with the monoclonal antibodies diluted in PBT (1:20 for B/3D6 and Y/1F4, and 1:250 for 1/2H7) for 60 min. The cells were then incubated sequentially with anti-mouse biotin (Amersham; 1:100) for 60 min and Texas-red streptavidin (Amersham 1:50) for 30 min.

and did not give any staining in immunofluorescence on cultured chromaffin cells (Fig. 2). The 140K protein detected by 1/2H7 was restricted in its distribution to the nuclear region of the cells. This staining of the nucleus was not always uniform but was restricted in some cases to the region facing the plasma membrane, on the side opposite the bulk of the cytoplasm (Fig. 2*a* and *b*). This staining pattern found with 1/2H7 indicates that the 140K protein is either a component of endoplasmic reticulum (ER) membranes closely associated with the nuclear envelope, or a component of the nuclear envelope itself. Using immunoblotting, we found the 140K protein to be present in a microsomal fraction of adrenal medulla, suggesting that the protein is in the ER (data not shown). By contrast, the 100K protein recognized by Y/1F4 was found to be diffusely distributed in chromaffin cells (Fig. 2*c, d*). The distribution of the 100K protein was not due to its being a component of the secretory granules (data not shown).

This variation in the distribution of the 140K and 100K proteins was found to correspond to the spatial organization of the calcium signals induced by stimuli that act through different calcium stores. First, the site of the rise in $[Ca^{2+}]_i$ in response to agonists such as methacholine, angiotensin I and angiotensin II was established in single fura-2-loaded cells by video imaging[9-11] and the nucleus was then located by staining the same cells with ethidium bromide. We had previously shown that rises in $[Ca^{2+}]_i$ in chromaffin cells in response to $Ins(1,4,5)P_3$-generating agonists, are spatially restricted and are initiated in one pole of the cells[9,10]. These rises occur even in the absence of external calcium. About 60% of cells showed a polarized rise in $[Ca^{2+}]_i$, and in these cells, challenged with methacholine ($n = 22$), angiotensin I ($n = 11$) or angiotensin II ($n = 17$), the rise in $[Ca^{2+}]_i$ originated in a region of the cell between the nucleus and the plasma membrane (Fig. 3*a*). Thus, the $Ins(1,4,5)P_3$-sensitive calcium store and the 140K Ca^{2+}-ATPase share a similar localization close to the nucleus in chromaffin cells. Recent cell fractionation studies[12] and the immunocytochemical localization of the $Ins(1,4,5)P_3$ receptor[13] provide evidence that a portion of the ER is the $Ins(1,4,5)P_3$-sensitive calcium store. Our observation that the $Ins(1,4,5)P_3$-sensitive store in chromaffin cells lies near the nucleus is consistent with the finding that the ER surrounding the nucleus of cerebellar Purkinje cells stains with an antibody against the $Ins(1,4,5)P_3$ receptor[13]. The localization of the mobilizable calcium store next to the nucleus may be important in the regulation of events within the nucleus. In the bovine adrenal chromaffin cell, a rise in $[Ca^{2+}]_i$ due to release from the internal stores is relatively ineffective in eliciting secretion[9-11] but could regulate

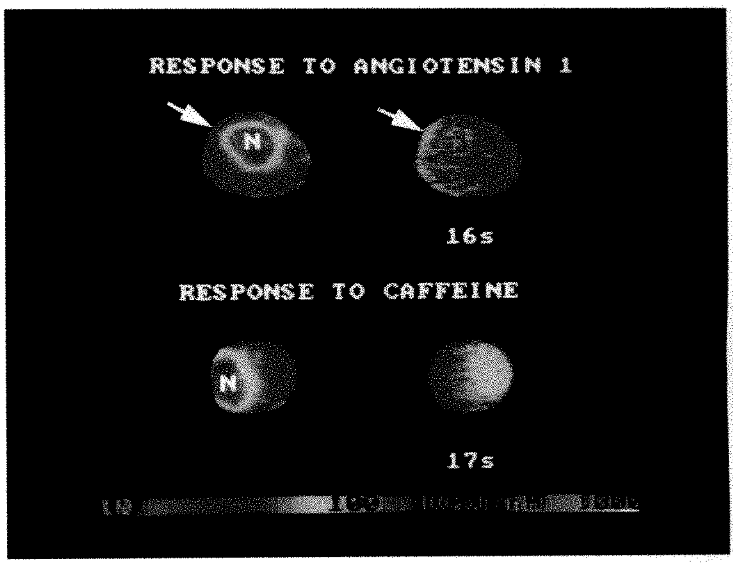

FIG. 3 Localization of the agonist-induced rise in $[Ca^{2+}]_i$ in the nucleus in chromaffin cells by video-imaging. False-colour images show on the left the location of the nucleus (N) in each cell and on the right the change in $[Ca^{2+}]_i$ due to 0.3 μM angiotensin I or 10 mM caffeine. In each case the basal $[Ca^{2+}]_i$ was subtracted from the level after stimulation so that the figures show the change in $[Ca^{2+}]_i$ from basal levels. The arrows point to the region with the highest rise in $[Ca^{2+}]_i$ (144 nM above basal; mean basal 60 nM) in response to angiotensin I. The maximum increase in $[Ca^{2+}]_i$ in response to caffeine in the cell shown was 139 nM above basal level (mean basal 64 nM).

METHODS. Imaging of $[Ca^{2+}]_i$ in single fura-2-loaded cells was carried out as described previously[9,10]. Fluorescent images were obtained by alternate excitation at 340 nm or 380 nm (40 ms at each wavelength) using an image-processing system (Imagine, Synoptics Ltd, Cambridge UK) interfaced to a DEC microvax II microcomputer. The ratio image was obtained at video rate and filtered with a time constant of 200 ms. Determination of $[Ca^{2+}]_i$ was as described by equation 5 of ref. 26. Finally, the cells were stained with 5 mg ml^{-1} ethidium bromide.

other aspects of cell function such as synthesis of biosynthetic enzymes and peptide precursors.

A different pattern of localization of $[Ca^{2+}]_i$ was seen in response to caffeine ($n = 31$), which also releases Ca^{2+} from internal stores in chromaffin cells[14]. In this case, the rise in $[Ca^{2+}]_i$ was low over the nucleus but occurred throughout the cytoplasm of the cells (Fig. 3*b*). Similar results were found in the absence of external calcium. It has recently been suggested[6] that the Ins(1,4,5)P_3-sensitive calcium store is the calciosome. This organelle in hepatocytes and pancreatic acinar cells is stained by a polyclonal antiserum against the skeletal muscle sarcoplasmic reticulum Ca^{2+}-ATPase[7]. This antiserum recognizes a 100K Ca^{2+}-ATPase-like protein in liver[15]. The calciosomes are distributed throughout the cytoplasm in many cell types, including adrenal chromaffin cells[7]. In agreement with these findings, we found that Y/1F4, which recognizes a 100K Ca^{2+}-ATPase-like protein, gives a diffuse staining pattern in chromaffin cells. As the rise in $[Ca^{2+}]_i$ in response to Ins(1,4,5)P_3-mobilizing agonists is usually spatially restricted in adrenal chromaffin cells[9,10], this indicates that the calciosomes are unlikely to be the Ins(1,4,5)P_3-sensitive calcium store. Instead, the calciosome is likely to be the caffeine-sensitive store because the rise in $[Ca^{2+}]_i$ following treatment with caffeine had a similar general distribution to that found for the 100K Ca^{2+}-ATPase-like protein.

The major finding of this study is that chromaffin cells possess two calcium stores which are spatially distinct and which differ in their sensitivity to Ins(1,4,5)P_3-mobilizing agonists, and possibly in the nature of their Ca^{2+}-ATPase. The possibility of the existence of two separate calcium stores, one sensitive to agonists that generate Ins(1,4,5)P_3 and one insensitive, has been inferred for a variety of other cell types[5,16–20]. In smooth muscle cells[17,20] and sensory neurons[18], the Ins(1,4,5)P_3-insensitive store is caffeine-sensitive. A similar situation appears to exist in chromaffin cells, where we have shown that the two stores are spatially distinct. The existence of two internal calcium stores has been invoked in one model for the mechanism of calcium oscillations[21] in response to Ins(1,4,5)P_3-generating agonists[22–24]. The ability to discriminate between these two stores in chromaffin cells may help in the dissection of the interactions and functional roles of the Ins(1,4,5)P_3-sensitive and Ins(1,4,5)P_3-insensitive stores in calcium signalling. □

PROTEIN kinase C (PKC) is believed to have a crucial role in synaptic transmitter release[1–4] and long-term potentiation[5–7]. An important substrate of PKC in the brain is the neuron-specific presynaptically localized protein B-50 (also termed GAP-43, F1, pp46 or P-57)[8–11]. B-50 has been implicated in the regulation of polyphosphoinositide metabolism[12,13] and calmodulin binding[14], and in the mechanisms of neurite outgrowth[15,16], long-term potentiation[17] and transmitter release[18]. It is still unknown, however, whether B-50 (and/or its phosphorylation) is essential to any of these processes. Here we report the results of studies in which antibodies to B-50, which interfere with B-50 phosphorylation, were introduced into rat cortical synaptosomes that were permeabilized with streptolysin-O (SL-O). We found that the release of [^{3}H]noradrenaline, induced by increasing the Ca^{2+} concentration in the buffer, is inhibited completely by the antibodies. These results provide the first demonstration of a causal relationship between the PKC substrate B-50 and the release of neurotransmitter.

Depolarization of intact rat cortical synaptosomes with 10 mM K^+ induced an efflux of noradrenaline (NA) (Fig. 1*a*, inset). This K^+-induced efflux was dependent on extracellular Ca^{2+}, confirming that in our system an influx of Ca^{2+} was the intracellular trigger for depolarization-induced neurotransmitter release. To introduce anti-B-50 IgG into synaptosomes, we used a SL-O permeation technique originally developed to study Ca^{2+}-induced vesicular histamine release from mast cells[19]. The effect of K^+ depolarization on NA release could be mimicked in SL-O-permeabilized synaptosomes by increasing the Ca^{2+} concentration in the incubation buffer from 10^{-7} to 10^{-5} M (Fig. 1*a*). To measure basal NA efflux, we used 10^{-7} M Ca^{2+} because (1) this is the resting, intracellular Ca^{2+} concentration in synaptosomes[20], and (2) a further reduction of the Ca^{2+} concentration to 10^{-8} M did not reduce NA efflux (see also Fig. 3). As in mast cells, the effect of Ca^{2+} on transmitter release could only be observed in a limited dose range of SL-O (0.6–2.0 IU ml^{-1}; Fig. 1*a*). The effect of Ca^{2+} was not due to an efflux of cytosolic NA, because Ca^{2+} did not stimulate the SL-O-induced efflux of the cytosolic marker protein, lactate dehydrogenase (Fig. 1*b*). This confirmed that the Ca^{2+}-dependent part of the SL-O-induced NA efflux was vesicular NA release. From our data we concluded that 0.8 IU ml^{-1} SL-O is the optimal concentration for permeation of the synaptosomes and for triggering the release of NA with Ca^{2+}.

We tested the effect of anti-B-50 IgG on the extent of endogenous B-50 phosphorylation in synaptosomes, measured with exogenous [γ-^{32}P]ATP as a phosphate donor. B-50 phosphorylation was only detectable after permeation of synaptosomes with SL-O (Fig. 2), because ATP does not penetrate the intact synaptosome. In control experiments in which H_2O-lysed synaptosomes were used, SL-O had no direct effect on overall kinase activity nor on B-50 phosphorylation. In the SL-O-permeabilized system, anti-B-50 IgG completely inhibited B-50 phosphorylation, whereas control IgG had no effect (Fig. 2). The inhibitory effect of anti-B-50 IgG was highly specific for the phosphorylation of B-50. These results demonstrate that the synaptosomes are sufficiently permeabilized to

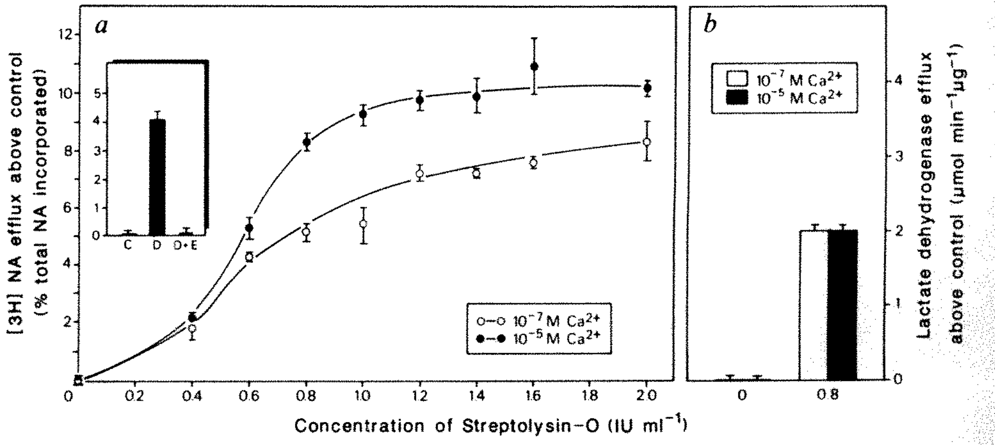

FIG. 1 *a*, Ca^{2+}-induced efflux of NA in SL-O-permeabilized synaptosomes. Synaptosomes were permeabilized with different concentrations of SL-O at 10^{-7} M (○) and 10^{-5} M (●) free Ca^{2+}. The inset shows Ca^{2+}-dependent K^+-induced release of NA in non-permeabilized synaptosomes (C, control; D, K^+-depolarized; D+E, K^+-depolarized in Ca^{2+}-free buffer). NA efflux above control is expressed as % of total NA incorporated. Control efflux (in the absence of SL-O) was 14.73% and 11.36% for Fig. 1*a* and Fig. 1*a* inset respectively. Data are expressed as mean ± s.e.m. ($n = 3$) *b*, Efflux of the cytosolic marker protein lactate dehydrogenase from permeabilized and non-permeabilized synaptosomes. Synaptosomes were treated as described below, except that lactate dehydrogenase activity instead of NA was measured in the supernatant. Control efflux (in the absence of SL-O) was 0.5 µmol min^{-1} $µg^{-1}$. Lactate dehydrogenase activity was determined according to Bergmeyer and Bernt[32].

METHODS. Rat cortical synaptosomes were isolated and labelled with NA according to De Langen *et al.*[31] using the buffer described in ref. 19, supplemented with 2 mM $CaCl_2$. They were then washed three times with buffer without $CaCl_2$ and resuspended at 2 mg protein ml^{-1}. Non-permeabilized synaptosomes (inset): synaptosomes (20 µg protein per 120 µl) were incubated for 5 min at 37 °C in buffer with 2 mM $CaCl_2$ (C), buffer containing 2mM $CaCl_2$ and 10 mM K^+ (D) or in buffer containing 10 mM K^+ and 1 mM EGTA (D + E). The samples were centrifuged for 30 s at 1,000*g*, supernatants were collected and counted in a liquid scintillation counter (Beckman 2000CA). Permeabilized synaptosomes: synaptosomes (20 µg protein per 120 µl) were incubated for 5 min at 37 °C in buffer containing various concentrations of SL-O (Wellcome, UK), 5 mM ATP, 2 mM $MgCl_2$ and Ca^{2+}-EGTA buffers with 10^{-7} M or 10^{-5} M free Ca^{2+} (ref. 19). Samples were then processed as described above.

introduce anti-B-50 IgG and that these antibodies specifically inhibit B-50 phosphorylation.

Next we incubated permeabilized synaptosomes with anti-B-50 IgG and applied the Ca^{2+} trigger, and measured NA release. Ca^{2+}-induced release of NA was inhibited by the anti-B-50 IgG in a concentration-dependent way (Fig. 3), whereas control IgG and heat-inactivated anti-B-50 IgG were ineffective at such inhibition. Neither control IgG nor anti-B-50 IgG affected NA efflux at 10^{-8} and 10^{-7} M Ca^{2+}, showing that the antibodies do not influence the Ca^{2+}-independent efflux.

We conclude that B-50 plays a crucial part in the molecular

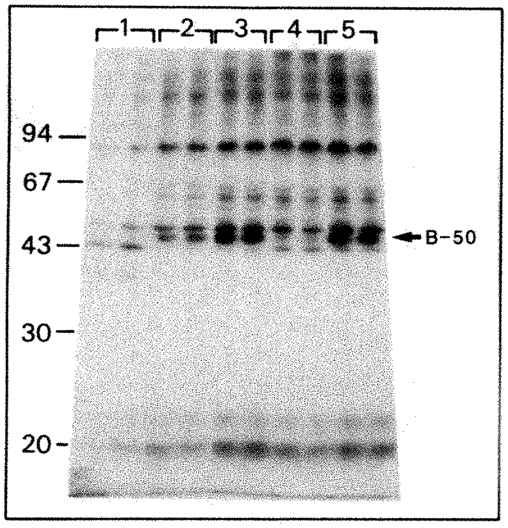

FIG. 2 Autoradiogram showing the effects of anti-B-50 IgG on endogenous protein phosphorylation in SL-O-permeabilized synaptosomes. Synaptosomes were treated with 0 (lanes 1), 0.4 (lanes 2), and 0.8 (lanes 3) IU ml^{-1} SL-O before phosphorylation with [γ-^{32}P]ATP. The effect of anti-B-50 IgG (lanes 4) or control IgG (lanes 5) was tested in synaptosomes permeabilized with 0.8 IU ml^{-1} SL-O. Position of relative molecular mass markers ($\times 10^3$) shown on left.

METHODS. Synaptosomes (10 µg protein) were permeabilized with SL-O for 5 min at 37 °C in 30 µl PIPES buffer containing 10^{-5} M Ca^{2+} without ATP. Phosphorylation was started by adding 2 µCi [γ-^{32}P]ATP (specific activity 3,000 Ci $mmol^{-1}$; Amersham, UK) and carrier ATP to a final concentration of 7.5 µM. After 15 s, phosphorylation was stopped and analysed as described[10]. IgG (10 µg per assay) were added simultaneously with SL-O. Anti-B-50 IgG was isolated from B-50 antiserum raised in rabbits as described previously[33] by affinity chromatography on a B-50 column[33]. Isolated anti-B-50 IgG was extensively dialysed against 1,000 volumes of double distilled water, freeze dried and stored dry at −80 °C. On western blots loaded with total synaptosomal proteins, we confirmed the IgG to be specific for B-50. The amount of IgG was determined according to Lowry *et al.*[34] with total rabbit IgG (Miles, UK) as reference. Total rabbit IgG was also used as control IgG.

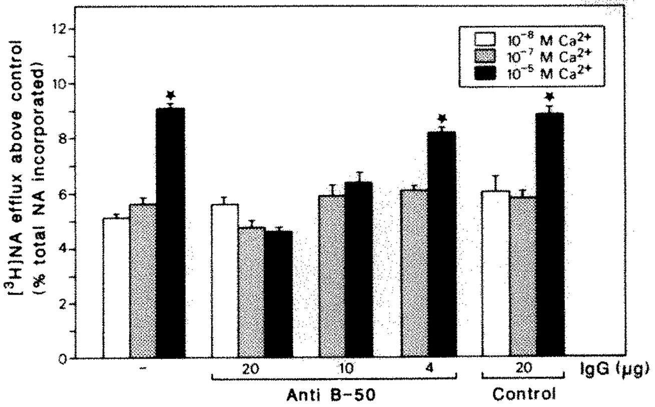

FIG. 3 Effect of anti-B-50 IgG on Ca^{2+}-induced release of NA from SL-O-permeabilized synaptosomes. Synaptosomes were permeabilized with 0.8 IU ml^{-1} SL-O and incubated without IgG (−), with different concentrations of anti-B-50 IgG (anti-B-50), or with control IgG (control) as described in Fig. 2 legend. Ca^{2+}-induced NA release was measured as described in Fig. 1 legend (open bars, 10^{-8} M Ca^{2+}; dotted bars, 10^{-7} M Ca^{2+}; filled bars, 10^{-5} M Ca^{2+}). Neither anti-B-50 nor control IgG (20 µg per assay) affected NA release in non-permeabilized synaptosomes. Data are expressed as mean ± s.e.m. (three independent experiments). Identical results were obtained in a separate experiment using a different batch of anti-B-50 IgG. Data were analysed by one-way analysis of variance (ANOVA) with a supplemental Newman-Keuls test. Asterisk denotes group significantly different ($P < 0.05$) from all groups treated with 10^{-7} or 10^{-8} M Ca^{2+}.

mechanism of NA release from rat cerebral-cortex synaptosomes. Because immunocytochemical studies have shown that B-50 is found in synapses throughout the brain[21,22], B-50 could be more generally involved in transmitter release. Three lines of evidence suggest that the phosphorylation of B-50 by PKC is essential for stimulus-secretion coupling during transmitter release: (1) phorbol esters that directly activate PKC enhance the release of a variety of neurotransmitters[1-4]; (2) by using an antibody-independent approach, we have previously shown that depolarization-induced neurotransmitter release from non-permeabilized synaptosomes and hippocampal slices is closely correlated with a PKC-mediated increase in B-50 phosphorylation[18,23]; and (3) here we have shown that anti-B-50 IgG inhibits B-50 phosphorylation as well as Ca^{2+}-dependent transmitter release. If B-50 phosphorylation by PKC is indeed involved in the mechanism of transmitter release, then a long-term increase in PKC-mediated B-50 phosphorylation[7,17] could be one of the mechanisms underlying the increase in the release of glutamate that occurs during long-term potentiation[5-7,24,25].

In view of the localization of B-50 at the inner leaflet of the plasma membrane[21,26], we suggest that B-50 is involved in the regulation of vesicle fusion with the plasma membrane, a process in which the vesicle-associated protein synapsin I (a substrate of calmodulin-dependent kinases) has also been implicated[27,28]. But the difference in the localization of phosphorylating enzymes of these two proteins indicates that they have distinct roles in the transmitter release process. It may be that the regulatory role of B-50 in vesicle fusion is not limited to transmitter release, but extends to membrane-fusion processes during neurite outgrowth[29,30]. It remains to be investigated to what extent calmodulin binding[14] and modulation of phosphatidyl inositol 4-phosphate kinate activity[12,13]—putative properties of B-50—are also involved in controlling neurotransmitter release. ☐

Production of antibodies in transgenic plants

Andrew Hiatt, Robert Cafferkey & Katherine Bowdish

Department of Molecular Biology, The Research Institute of Scripps Clinic,
10666 North Torrey Pines Road, La Jolla, California 92037, USA

COMPLEMENTARY DNAs derived from a mouse hybridoma messenger RNA were used to transform tobacco leaf segments followed by regeneration of mature plants. Plants expressing single gamma or kappa immunoglobulin chains were crossed to yield progeny in which both chains were expressed simultaneously. A functional antibody accumulated to 1.3% of total leaf protein in plants expressing full-length cDNAs containing leader sequences. Specific binding of the antigen recognized by these antibodies was similar to the hybridoma-derived antibody. Transformants having γ- or κ-chain cDNAs without leader sequences gave poor expression of the proteins. The increased abundance of both γ- and κ-chains in transformants expressing assembled gamma-kappa complexes was not reflected in increased mRNA levels. The results demonstrate that production of immunoglobulins and assembly of functional antibodies occurs very efficiently in tobacco. Assembly of subunits by sexual cross might be a generally applicable method for expression of heterologous multimers in plants.

The source of immunoglobulin mRNAs was a hybridoma cell line expressing a catalytic IgG_1 antibody (6D4) which binds a low molecular weight phosphonate ester (P3) and catalyses the hydrolysis of certain carboxylic esters. Constructs used for immunoglobulin expression in plants consisted of coding-length cDNAs of the 6D4 γ- or κ-chain with or without their leader sequences. These cDNAs were modified to contain terminal *Eco*R1 restriction enzyme digestion sites and were ligated into the constitutive plant expression vector pMON530 (ref. 2) to form pHi101 (kappa, no leader), pHi102 (kappa, leader), pHi201 (gamma, no leader) and pHi202 (gamma, leader). We transformed tobacco plants using Agrobacterium containing each of these four plasmids[3] and screened leaf extracts from regenerated transformants for the presence of immunoglobulin heavy or light chains by enzyme-linked immunosorbent assay (ELISA)[4]. Transformants expressing individual immunoglobulin chains were then sexually crossed to produce progeny expressing both chains. The results of the ELISA revealed high levels of kappa and gamma chains accumulating in individual plants containing DNA from both pHi102 and pHi202 (Table 1; Fig. 2*a*). We verified the expression of both heavy and light chains by western blotting (Fig. 1). From the ELISAs, we judged that virtually all the γ- and κ-chains in these plants were assembled into gamma-kappa complexes (Table 1). Western blots provided additional evidence for assembled antibodies in that, under non-reducing conditions, most of the immunoreactive γ- and κ-chains aggregated at a high molecular weight (Fig. 1).

The binding specificity of the assembled gamma-kappa complexes was studied in ELISAs in which a P3-bovine serum albumin conjugate was used as antigen. The antigen binding by antibody derived from plants was equivalent to antigen binding by the 6D4 hybridoma antibody. Incubation of plant extracts or the purified 6D4 antibody with 50 $\mu mol\ l^{-1}$ P3 for 3 h at 25 °C before addition to the ELISA eliminated antibody binding to the P3-BSA conjugate, demonstrating that binding was specific for the P3 hapten. Half-maximal inhibition occurred with 10 $\mu mol\ l^{-1}$ free P3 for both hybridoma and plant-derived antibodies.

Transformants derived from the leaderless constructs pHi101 and pHi201 contained very low levels of κ- and γ-chains respectively, but Southern and northern blots (Fig. 2) demonstrated the presence of transforming DNA and immunoglobulin transcripts. None of the plants expressing leaderless immunoglobulin chains contained assembled gamma-kappa complexes (Table 1).

The increased recovery of immunoglobulin epitopes from transformants expressing full-length cDNAs was not reflected in increased mRNA transcript levels. Northern blots (Fig. 2*b*) comparing pHi201 and pHi202 transformants, for example, revealed nearly equivalent levels of heavy-chain transcripts, although ELISAs indicated a 40-fold increase in accumulation of heavy-chain protein in the pHi202 transformant. Likewise, immunoglobulin mRNA levels in a plant producing large amounts of assembled antibodies were not significantly different from the parental plants that accumulated low levels of immunoglobulin chains (Fig. 2*b*).

Our results show that individual cDNAs for immunoglobulin κ- and γ-chains can be efficiently expressed in tobacco to form functional antibodies. Assembly of immunoglobulin chains by sexual cross in plants represents a useful alternative to the expression by a single vector of both gamma and kappa cDNAs as in yeast or bacteria[5-7], or double transformation with vectors containing individual cDNAs[8,9]. Potentially, this method is applicable to the assembly of oligomers other than antibodies. The characterization of antibodies produced in plants (glycosylation, processing of leader sequences, cytolocalization and turnover) will be described in a later paper.

In B lymphocytes, immunoglobulin processing and assembly occurs in the endoplasmic reticulum/Golgi in a process that may be promoted by heavy-chain binding proteins present in the endoplasmic reticulum[10,11]. Plant cells may also have a system for multimer assembly in their endoplasmic reticulum/Golgi that can recognize immunoglobulin chains. Alternatively, assembly may occur spontaneously, given sufficient levels of each chain in the appropriate cellular compartment. Our results demonstrate that plants require a signal sequence for efficient assembly of γ- and κ-subunits. The presence of the mouse leader sequence clearly augments the accumulation of individual chains. This might be the result of an enhanced translation of the immunoglobulin messengers or an increased stability of each protein as a result of subcellular sequestering or secretion. The yield of each chain is increased in plants expressing both gamma and kappa, indicating that assembly of the gamma-kappa complex might enhance stability.

TABLE 1 Expression and assembly of immunoglobulin gamma and kappa chains in tobacco

Accumulation of γ- or κ-chains in transformed plants*

γNL	**γL**	**γL(κL)**	**γNL(κNL)**
30 ± 16 (60)	1,412 ± 270 (2,400)	3,330 ± 2,000 (12,800)	32 ± 26 (60)
κNL	**κL**	**κL(γL)**	**κNL(γNL)**
1.4 ± 1.2 (3.5)	56 ± 5 (80)	3,700 ± 2,300 (12,800)	6.5 ± 5 (20)

Distribution and assembly in crosses†

	γ only	**κ only**	**γκ**	**Null**
κNL × γNL	4	6	3 (0% assembly)	5
κL × γL	3	10	11 (95 ± 16% assembly)	4

* Accumulation of individual gamma and kappa chains (in ng per mg total protein) was estimated by ELISA[4]. Microtitre wells were coated with a goat anti-mouse heavy or light chain-specific IgG (Fisher) in 150 mM NaCl, 20 mM Tris-HCl, pH 8.0 (TBS), followed by blocking with 5% non-fat dry milk in TBS. Plant leaves were homogenized in a mortar and pestle at 4 °C after removal of the midvein. To the supernatant a quarter volume of 5 × TBS was added, and 50 μl of 1 in 2 serial dilutions were added to each microtitre well. After 18 h at 4 °C, microtitre wells were washed with distilled water at room temperature. Bound γ- or κ-chains were reacted with goat anti-mouse heavy or light chain-specific antibodies conjugated to horseradish peroxidase for 2 h at 37 °C in TBS, and detected according to the manufacturer's instructions. Control microtitre wells contained extracts from plants transformed with pMON530 vector. Values given as mean (± s.d.) are derived from at least two determinations per plant and do not include transformants producing no detectable γ- or κ-chain. At least nine plants were assayed in each category. All values are given as ng per mg of total protein in the extract and are derived from the quantity of purified 6D4 antibody required to given an equivalent colour development in ELISA. Total protein in the extract was determined by the Bio-Rad Coomassie assay. Complementary DNAs containing no leader sequences are referred to as γNL and κNL; γL and κL refer to cDNAs with leader sequences; γ(κ) refers to gamma chains in a plant that also expresses κ-chains, and vice versa. Numbers in parentheses are values for plants with the highest levels of accumulation.

† The number of plants expressing γ- or κ-chains among the progeny of a sexual cross. The ELISA for assembly used horseradish peroxidase-conjugated anti-κ-chain-specific antibodies to detect antigen bound to microtitre wells coated with unlabelled anti-γ-chain-specific antibodies, and vice versa. Values derived from these assays were used to calculate the per cent of assembly by comparison with the purified 6D4 antibody. This was determined at least three times for each γκ plant. The per cent assembly is expressed in parentheses as the mean ± s.d.

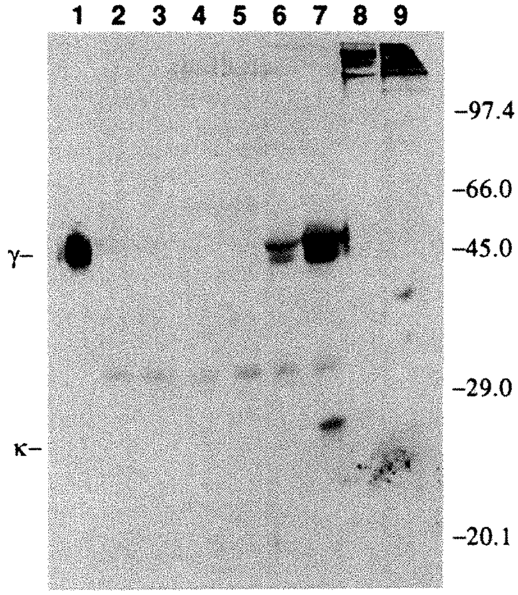

FIG. 1 Western blot of leaf proteins from transgenic tobacco plants expressing immunoglobulin chains. Leaf segments (1 g) from mature plants were homogenized in a mortar and pestle with 1 ml 0.05 M Tris-HCl, pH 7.5, 1 mM phenylmethanesulphonyl fluoride. Extracts were boiled in 4 M urea, 1% SDS, with or without 2 mM dithiothreitol (DTT) as indicated, for 3 min. SDS-PAGE in 10% acrylamide[16] and blotting of the proteins to nitrocellulose[17] were performed as described. Blots were preincubated for 6 h at 4 °C in 20 mM Tris-HCl, pH 8.0, 150 mM NaCl, 0.01% Tween 20 (TBST) containing 5% BSA, and 0.5% non-fat dried milk before the addition of antibodies. A biotinylated goat anti-mouse whole IgG antibody (Cappel), diluted 1:500 in TBST was used to probe the blots at 4 °C for 24 h. A variety of commercially available antibodies (anti-mouse IgGs) were used in other experiments with similar results. Antibody binding was visualized after binding of streptavidin-conjugated alkaline phosphatase (25 °C, for 2 h) by incubation in 300 μg ml^{-1} nitroblue tetrazolium and 150 μg ml^{-1} 5-bromo-4-chloro-3-indolyl phosphate. In lanes 1–7, 40 μl of each extract containing DTT; lanes 8 and 9, 40 μl extract without DTT. Lane 1, 100 ng purified antibody from the 6D4 hybridoma; lane 2, 15 μg wild-type plant-extract protein; lane 3, 15 μg protein from a plant transformed with truncated κ-chain cDNA (pHi101) containing no leader sequence; lane 4, 15 μg from plant transformed with truncated γ-chain cDNA (pHi201); lane 5, 15 μg from a full-length kappa cDNA transformant (pHi102); lane 6, 15 μg from a full-length γ-chain cDNA transformant (pHi202); lane 7, 15 μg from an F1 plant derived from the cross between a kappa and a gamma producer; lane 8, 100 ng 6D4 antibody (no DTT); lane 9, same as lane 7, except no DTT. Gamma and kappa on the left refer to the positions of the 6D4 heavy and light chains; positions of molecular weight (given in thousands) markers are shown on the right. By ELISA, extracts in lanes 3–5 contained very low levels of κ- or γ-chains (<0.008% of total protein, Table 1), whereas extracts in lanes 6, 7 and 9 contained 0.24, 1.3 and 1.3% immunoglobulin respectively.

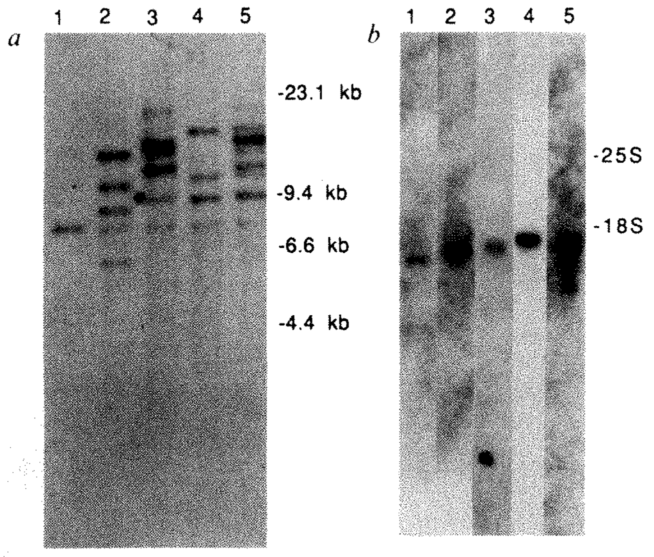

FIG. 2 Southern and northern blots of leaf DNA and RNA from transgenic plants expressing immunoglobulin cDNAs. *a*, DNA was extracted from 1 g mature leaf tissue after freezing the fresh segments in liquid N_2. Homogenization into urea mix[18] was in a mortar and pestle. The homogenate was extracted with phenol:$CHCl_3$ (1:1) and the nucleic acids precipitated by addition of one volume of isopropyl alcohol. The resuspended DNA (20 μg each) was cut with *Hin*dIII and Southern-blotted as described[19]. The probe used for both Southern and northern blots was ^{32}P-labelled pMON530 plasmid[2] containing either a kappa cDNA or a gamma cDNA. Both cDNAs were used in the hybridization shown. Lane 1, DNA from a transformant expressing a light-chain cDNA without a leader sequence (pHi101); lane 2, DNA from a heavy-chain cDNA transformant, no leader (pHi201); lane 3, DNA from a transformant expressing full-length light chain with leader (pHi102); lane 4, DNA from a transformant expressing heavy chain with leader (pHi202); lane 5, DNA from an F_1 plant derived from a cross between plants expressing full-length gamma or kappa cDNAs (pHi102 × pHi202). *b*, Extraction of RNA from 1 g fresh leaf tissue was by homogenization in 10 ml 0.1 M Tris-HCl, pH 9.0, and 10 ml phenol saturated with this buffer, using a Polytron at high speed. Nucleic acids were precipitated by addition of one tenth volume 3.0 M sodium acetate, pH 5.0, and 1.5 volumes isopropyl alcohol. Resuspended RNA was electrophoresed in gels containing formaldehyde and northern blotted onto nylon membranes (Amersham) as described[19]. Lane 1, RNA from a transformant expressing a light-chain cDNA without a leader sequence (pHi101); lane 2, RNA from a heavy-chain cDNA transformant, no leader (pHi201); lane 3, RNA from a transformant expressing full-length light chain with leader (pHi102); lane 4, RNA from a transformant expressing heavy chain with leader (pHi202); lane 5, RNA from an F_1 plant derived from a cross between plant expressing full-length gamma or kappa cDNAs (pHi102 × pHi202). Total RNA (20 μg) was loaded in each lane. Lanes from separate hybridizations were aligned with respect to the 18S (1,900 base pairs) and 25S (3,700 base pairs) ribosomal RNA bands on the blots, detected by methylene-blue staining.

Expression of functional antibodies from transcripts that do not contain signal sequences may require modifications to yield alternative antigen-binding structures (such as single-chain antigen-binding proteins[6,7]) that do not need to be assembled. Thus binding of constituents of metabolic pathways involved in morphogenesis, stress responses or plant-pathogen interactions could be used to further our understanding of these processes in a way analogous to the blocking by microinjected antibodies of specific protein functions in mammalian cells[12,13].

As large macromolecules such as protein multimers do not pass through plant cell walls[14,15], the binding by antibodies of small organic molecules (toxins, herbicides, plant hormones, organic chelates, for example) that are permeable to the cell wall might result in the net uptake and retention of these molecules in the plant. Accumulation of functioning antibodies may provide new options for the recovery of an array of environmental contaminants, as well as other biologically significant organics. Catalytic processing of small molecules within cell wall boundaries by antibodies may also become a generalized strategy for the elimination or modification of permeable organic compounds and could introduce new catalytic properties into existing metabolic pathways. ☐

Leu-8/TQ1 is the human equivalent of the Mel-14 lymph node homing receptor

David Camerini, Stephen P. James*, Ivan Stamenkovic† & Brian Seed

Departments of Molecular Biology, Massachusetts General Hospital, Genetics and † Pathology, Harvard Medical School, Boston, Massachusetts 02114, USA
* Section on Mucosal Immunity, Laboratory of Clinical Investigation, National Institute of Allergy and Infectious Diseases, Bethesda, Maryland 20892, USA

THE human pan-leukocyte antigen Leu-8 has attracted wide interest because its presence or absence identifies suppressor-inducer and helper-inducer $CD4^+$ T-lymphocyte subsets respectively. We report here that Leu-8 is the human homologue of the mouse Mel-14 homing receptor, a molecule that promotes the initial adhesion of blood-borne lymphocytes to the specialized post-capillary endothelium of peripheral lymph nodes. We also show that Leu-8 can adopt both conventional and phospholipid anchored forms, a finding that may have relevance in the context of antigen shedding following activation or homing. The assignment of lymphocytes to different functional classes based on lymph node homing potential may represent a more general association between lymphocyte function and tissue distribution.

Two complementary DNA clones encoding Leu-8 determinants were isolated from a human T-cell library by methods previously described[1,2]. DNA sequence analysis showed that the longer insert of the two contains 2,350 residues, whereas the shorter lacks 436 internal residues but is otherwise identical (Fig. 1). The predicted polypeptide sequences were found to diverge at their C-termini.

The protein encoded by the larger insert bears a strongly hydrophobic putative membrane spanning domain near its C terminus, followed by several positively charged residues resembling a cytoplasmic anchor sequence. The protein is closely related to the recently described murine Mel-14 homing receptor[3,4] (Fig. 1) and the corresponding cDNA sequence shares

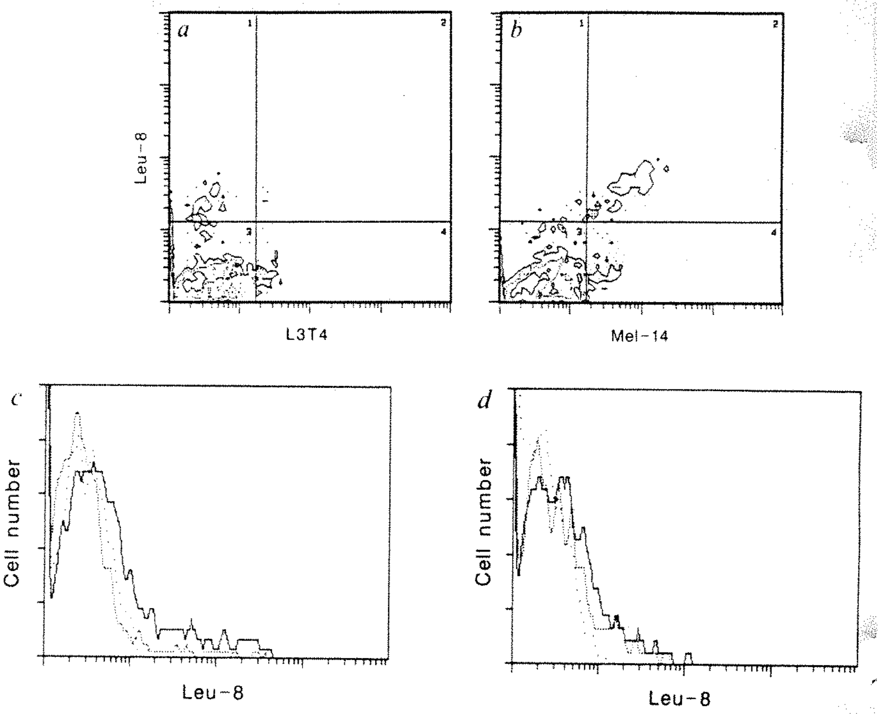

FIG. 2 Flow cytometric analysis of COS cells transfected with Leu-8 cDNA clones. *a, b,* Two-colour analysis with a phycoerythrin-conjugated anti-Leu-8 antibody (Leu-8 PE) and *a,* rat hybridoma L3T4 (control) ascites followed by fluorescein conjugated goat anti-rat IgG (fluorescein isothiocyanate (FITC) goat anti-rat IgG) or *b,* rat hybridoma Mel-14 ascites followed by FITC goat anti-rat IgG. *c, d,* Sensitivity of Leu-8 antigen to release by phosphatidylinositol-specific phospholipase C. COS cells expressing the shorter Leu-8 cDNA clone, *c,* or the longer clone *d,* were incubated with anti-Leu-8 FITC after incubation with phosphatidylinositol-specific phospholipase C or buffer alone at 37 °C for 1 h. In *c* and *d,* the histogram of CD16 (control) transfected COS cells stained with labelled anti-Leu-8 is represented by a sparsely dotted line, the histogram of Leu-8 transfected cells stained with labelled anti-Leu-8 is represented by a solid line, and the histogram of Leu-8 transfected cells treated with phospholipase C and similarly stained is represented by a broken line.

METHODS. For two-colour analysis, COS cells were trypsinized 12–24 h after DEAE-Dextran transfection and passaged in a ratio of 1:2. Post-transfection (60–72h), the cells were collected by incubation in PBS medium plus 0.5 mM EDTA (PBSE), collected by centrifugation, and resuspended in RPMI medium containing 10% human plasma. L3T4 or Mel-14 ascites was added at 1:50 dilution, and the cells were incubated on ice for 30–40 min, and centrifuged through PBS, 2% Ficoll, 1 mg ml^{-1} BSA, 0.04% sodium azide (PFBA). The cells were resuspended in PBSE with 20% skim milk containing affinity purfied FITC conjugated goat anti-rat IgG (Chemicon) at 50 μg ml^{-1}. After 20 min on ice, the cells were diluted with PBS plus 0.5 mM EDTA, and centrifuged through a two-step gradient of PFBA (0.25 ml) over PBS with 4% formaldehyde (2.5 ml). The cells were allowed to fix for 15 min, then the supernatant was aspirated, and the pellet and cells adhering to the walls of the tube were resuspended in IMD medium containing 0.02% Nonidet P-40 detergent, and recentrifuged. Anti-Leu-8 PE was added, the cells were incubated on ice for 30 min and then centrifuged through PBS, with 4% formaldehyde and 0.05% Tween-20, and stored for cytometry. For single-colour analysis, the primary antibody was added to the cells in PBS with 0.02% NaN$_3$ and 5% fetal bovine serum and incubated for 1 h on ice. Cells were washed as for the two-colour analyses. Incubation with phosphatidylinositol-specific phospholipase C was for 1 h at 37 °C in 2.6% glycerol and PBS at a ratio of 9:1.

single copy gene (Fig. 3). RNA blot hybridization revealed a major transcript of ~2.4 kilobases (kb) present in peripheral blood mononuclear cells, tonsillar B cells, and several lymphocytic cell lines; and a minor transcript of 2.0 kb, present in peripheral blood mononuclear cells, and the Jurkat and HSB-2 leukaemic T-cell lines (Fig. 3, and data not shown). Reduced expression of the RNA was detected in peripheral blood lymphocytes activated with phorbol ester plus either phytohaemagglutinin or concanavalin A, whereas treatment with phorbol ester alone induced transcript expression (Fig. 3). Tonsillar B cells activated by anti-IgM antibody, phorbol diester, anti-CD20 monoclonal antibody, G28-8 monoclonal antibody, or gamma interferon showed little change in transcript abundance (Fig. 3).

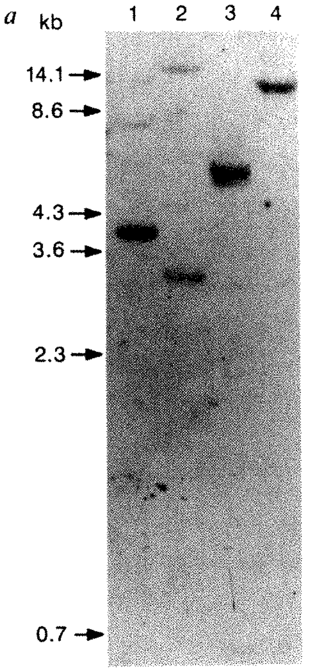
Western blot analysis allowed at least seven species of similar molecular weight to be visualized from extracts of Leu-8-transfected COS cells (Fig. 3). Extracts prepared from the human T-cell leukaemia line Jurkat, which expresses Leu-8 transcripts and surface antigen (data not shown), showed at least two closely spaced bands with a relative molecular mass of ~76,000 (76 K), the size of the largest forms seen in COS cells.

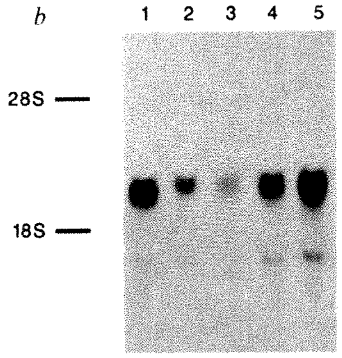
Twelve hours after activation by phorbol ester plus phytohaemagglutinin, Leu-8 expression by peripheral blood lymphocytes is diminished, whereas Leu-8 transcripts are more prevalent (Fig. 4). At 24 h post-treatment, both surface and transcript expression are substantially reduced (Fig. 4). Thus, surface Leu-8 is lost more rapidly than predicted by RNA turnover, possibly by shedding of a phosphatidylinositol-linked form[12]. Leu-8 loss on activation is consistent with serological studies showing that Leu-8 is a marker of resting lymphocytes in peripheral lymph nodes[13].

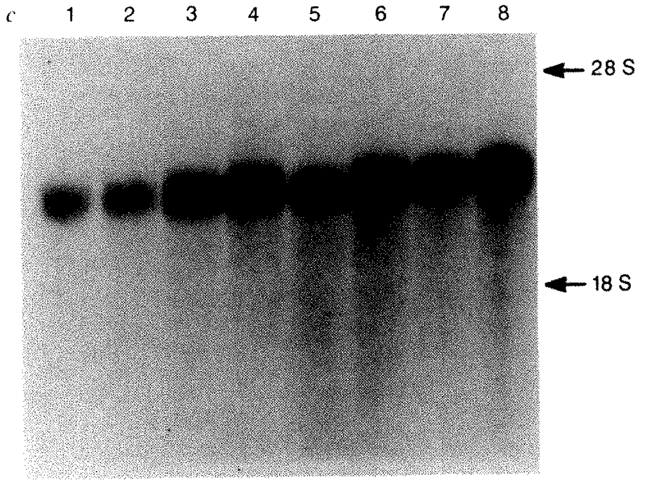
The tissue distributions of Leu-8 (refs 14–20) and Mel-14 antigen[9,23] are similar, with one exception[24,25]. Although Leu-8 is found on almost all medullary and scattered cortical thymocytes[26], histological studies have shown Mel-14 reactivity only on scattered cortical cells[27]. On this basis it has been proposed that murine cortical thymocytes are mature[27]; flow cytometry, however, has shown that most mature thymic cells are Mel-14$^+$ (ref. 28). The present data support the view that the failure to detect Mel-14 reactivity on thymic medullary cells *in situ* is an unusual histological artefact[28].

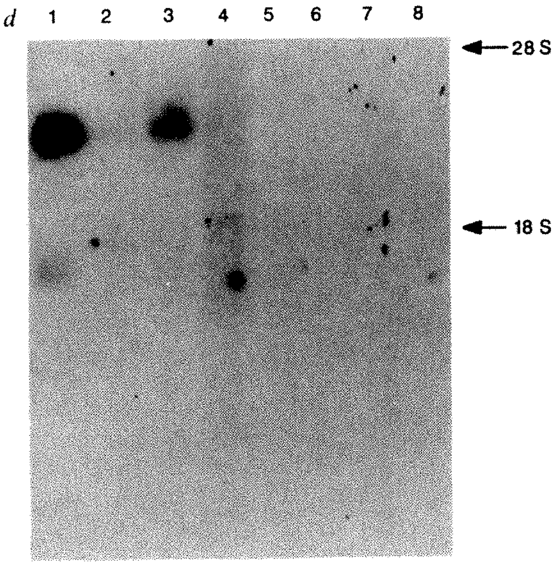
Among human peripheral blood T cells, the CD4$^+$ Leu-8/TQ1$^-$ subset bears almost all of the cells providing help for B cell IgM and IgG synthesis[8,14], whereas CD4$^+$ Leu-8$^+$ cells directly inhibit pokeweed mitogen-induced IgG synthesis[29]. Because T cells that promote immunoglobulin synthesis might be expected to target to, or reside in, peripheral nodes, the finding that CD4$^+$ Leu-8$^-$ cells provide B-cell help is unexpected. One explanation may be that this subset lacks Leu-8 because it consists of activated cells which have exited the nodes into the peripheral circulation. Consistent with this, the mitotically dormant paracortical and interfollicular areas of peripheral nodes bear Leu-8$^+$ T cells, whereas the actively proliferating B-cell germinal centres contain scattered Leu-8$^-$ T cells[26]. Another explanation for why CD4$^+$ Leu-8$^-$ cells provide B-cell help may be that the peripheral pool of cells providing help for immunoglobulin synthesis mainly arises (under normal physiological circumstances) from gut lymphatic structures, where chronic antigenic stimulation ensures a constant supply of activated T cells.

Because both Leu-8$^+$ and Leu-8$^-$ cells can be found among CD4$^+$ cells proliferating in response to a recall antigen, Leu-8 antigen loss following activation may be reversible on at least a subset of cells, and some memory cells may be Leu-8$^+$ (ref. 30). The CD4$^+$ Leu-8$^-$ population contains all of the cytotoxic









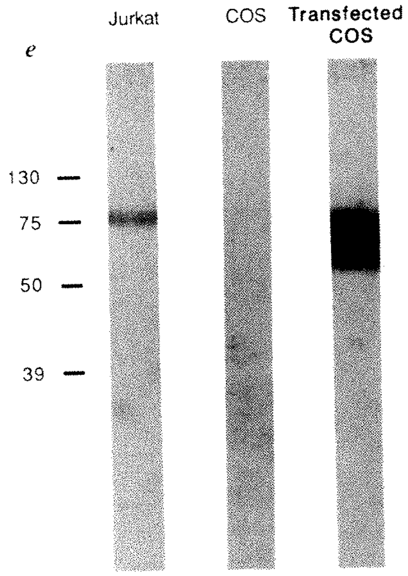


FIG. 3 Leu-8 protein and nucleic-acid analyses. *a*, DNA blot analysis of human DNA digested with *Bam*HI (lane 1), *Eco*RI (lane 2), *Hin*dIII (lane 3) and *Pst*I (lane 4) using a single-stranded Leu-8 probe. *b–e*, RNA blot analysis of total human RNA with a Leu-8 probe. *b*, Effect of activation on Leu-8 RNA expression by peripheral blood lymphocytes: lane 1, resting lymphocytes; lane 2, lymphocytes stimulated with 5 μg ml^{-1} phytohaemagglutinin plus 1 ng ml^{-1} phorbol myristate acetate (PMA); lane 3, lymphocytes stimulated with 5 μg ml^{-1} concanavalin A plus 1 ng ml^{-1} PMA; lane 4, lymphocytes stimulated with pokeweed mitogen (GIBCO, 1:100); lane 5, lymphocytes stimulated with 1 ng ml^{-1} PMA. *c*, RNA from resting and stimulated B cells: lane 1, B cell-enriched peripheral blood lymphocytes stimulated with 1 μg ml^{-1} γ-interferon (Hoechst); lane 2, unstimulated B cell-enriched resting peripheral blood lymphocytes; lane 3, purified tonsillar B cells stimulated with 5 μg ml^{-1} G28-8; lane 4, purified tonsillar B cells stimulated with 5 μg ml^{-1} anti-CD20 antibody 1F5; lane 5, resting purified tonsillar B cells; lane 6, purified tonsillar B cells stimulated with 1 μg ml^{-1} γ-interferon; lane 7, purified tonsillar B cells stimulated with 20 ng ml^{-1} PMA; lane 8, purified tonsillar B cells stimulated with 50 μg ml^{-1} anti-IgM antibody; *d*, T- and myeloid cell line RNAs. Lane 1, HSB-2; lane 2, Molt4; lane 3, Hut78; lane 4, HL60; lane 5, HL60 stimulated with 50 μg ml^{-1} PMA; lane 6, U937; lane 7, U937 stimulated with 50 μg ml^{-1} PMA; lane 8, ThP-1. *e*, Protein blot transfer analysis of Leu-8. Jurkat (T cell leukaemia) cells, COS cells, or COS cells transfected with the longer Leu-8 clone were solubilized in a lysis buffer containing 1% NP-40 and fractionated on 10% SDS polyacrylamide gels. The fractionated proteins were transferred to nitrocellulose electrophoretically. The filter replica was blocked with gelatin (1% in Tris-buffered saline), treated with anti-Leu-8 ascites (1:10,000), washed, and incubated with goat anti-mouse IgG antibody coupled to alkaline phosphatase (Bio-Rad, 1:1000). Bands were visualized by incubation with nitroblue tetrazolium-bromo-chloroindolyl phosphate (Bio-Rad).

METHODS. DNA and RNA blot hybridizations were carried out as previously described[1,2]. Tonsillar B cells were prepared by teasing the tissue in sterile phosphate-buffered saline. Tonsillar or peripheral blood mononuclear cells were washed several times and T cells were removed by incubating with anti-CD3 monoclonal antibody at 4 °C followed by rabbit complement (Pel-Freez) at 37 °C for 45 min in serum-free IMD medium (GIBCO). Monocytes were removed by adherence to plastic dishes, twice for 30 min. 80–85% of the resulting cells were sIgM-positive.

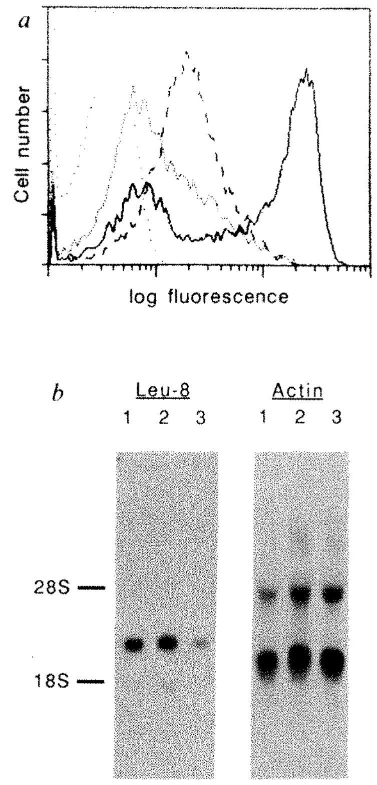

FIG. 4 Leu-8 RNA and surface expression following activation. Peripheral blood lymphocytes were stimulated for the times indicated with 5 μg ml^{-1} phytohaemagglutinin (PHA) and 1 ng ml^{-1} PMA. *a*, Flow cytometric analysis of Leu-8 antigen on cells exposed to 0, 12 and 24 h of stimulation. ——, Untreated; – – –, PHA+PMA (12 h); ·····, PHA+PMA (24 h); · · ·, no stain. *b*, RNA blot analysis of the cells shown in *a*, with a Leu-8 cDNA probe. Lane 1, no treatment; lane 2, stimulated for 12 h; lane 3, stimulated for 24 h. *c*, Hybridization of the blot in *b* with an actin cDNA probe.

(class II restricted) effector cells, whereas only the CD4$^+$ Leu-8$^+$ population proliferates in long-term culture without exogenous cytokine, indicating that this population provides autocrine T-cell help[30]. As the Leu-8 phenotype of these populations is stable on continued culture *in vitro*[30], the CD4$^+$ Leu-8$^-$ cytotoxic/immunoglobulin helper cells may be destined to invade the mucosal lymphatics or extralymphoid sites of inflammation, whereas the CD4$^+$ Leu-8$^+$ autocrine helper cells recirculate through peripheral nodes. ☐

Interleukin-2-dependent autocrine proliferation in T-cell development

María L. Toribio, José C. Gutiérrez-Ramos, Luis Pezzi, Miguel A. R. Marcos & Carlos Martínez-A.

Centro de Biología Molecular (CSIC), Universidad Autónoma de Madrid, Cantoblanco 28049-Madrid, Spain

ACTIVATED T lymphocytes proliferate in response to interleukin-2 (IL-2), which binds to a specific high-affinity receptor (IL-2R)[1–3]. This consists of at least two noncovalently linked polypeptides, p55/IL-2Rα (Tac)[4] and p75/IL-2Rβ[5–7]. Both molecules bind IL-2 independently, with low and intermediate affinity respectively[5–10], but only IL-2Rβ is thought to mediate IL-2 signal transduction[8,11–13]. Although IL-2Rβ seems to be constitutively expressed on resting T lymphocytes[9,14], the growth of these T cells is specifically induced by antigenic triggering by the T-cell receptor (TCR), which then results in the transcription of both IL-2 and IL-2Rα genes[1,2,15]. By contrast, activation of the IL-2/IL-2R pathway in the thymus seems to precede the appearance of the TCR, as IL-2Rα is expressed on T-cell precursors lacking TCR[16–21]. The basis for IL-2R expression by immature thymocytes, however, remains largely unknown. We show here that IL-2Rα-negative T-cell precursors constitutively express IL-2Rβ and produce their own IL-2. The IL-2/IL-2Rβ interaction on these cells induces the expression of IL-2Rα, leading to high-affinity IL-2R display and cellular proliferation. We suggest that this IL-2-dependent autocrine pathway of growth stimulation plays a key role in the intrathymic development of mature T cells.

Adult human thymocytes expressing the CD7 T-cell antigen, but lacking the CD1, CD2, CD3, CD4 and CD8 molecules (pro-T cells), comprise the precursors of IL-2Rα^+ thymocytes and mature T cells[21,22]. Although very few pro-T cells express IL-2Rα (<1% Tac$^+$; Fig. 1*a*), Scatchard analyses of ^{125}I-labelled IL-2 binding indicates that there are ~3,250 IL-2 binding sites per cell (assuming a uniform distribution of sites) (Fig. 2*a*). A large majority (3,000 sites per cell) bound IL-2 with the 'intermediate' affinity characteristic of IL-2Rβ ($K_d \sim 1.9$ nM)[7,8], whereas only 250 high-affinity receptors per cell ($K_d \sim 26$pM) were detected. Parallel studies conducted in the presence of saturating concentrations (500-fold molar excess) of anti-IL-2Rα monoclonal antibody, showed that pro-T cells displayed 2,320 sites per cell ($K_d \sim 850$pM), other than IL-2Rα (Fig. 2*b*). This suggests that the IL-2Rβ intermediate-affinity receptor is the chief IL-2-binding component expressed on pro-T cells. By contrast, an almost threefold lower number of IL-2Rβ was detected in highly purified, resting peripheral T cells (960 sites per cell, $K_d \sim 820$pM) (Fig. 2*c*).

According to these data, freshly isolated pro-T cells contained virtually no detectable IL-2Rα messenger RNA (Fig. 3*a*). Incubation of pro-T cells with doses of recombinant IL-2 (rIL-2) favouring intermediate-affinity binding (1nM), however, resulted in a rapid induction of IL-2Rα gene transcription, which reached maximal levels after eight days (similar to those observed in mitogen-activated peripheral T cells, Fig 3*a*) This induction led to the expression of IL-2Rα molecules on most cultured pro-T cells (86%, Fig 1*b*) A similar proportion of IL-2Rα^+ cells (with a reduced fluorescence intensity, probably secondary to the antibody treatment) was observed when a 300-fold molar excess of anti-IL-2Rα monoclonal antibody was added to the cultures (81%, Fig 1*c*) Binding of IL-2 to individual IL-2Rβ molecules may, therefore, be an effective signal for the induction of IL-2Rα on T-cell precursors The observation that expression in both culture conditions of IL-2Rα was detectable on 5 to 30% of cells after only 24 h of culture, when the cellular recovery was ~70%, formally rules out overgrowth of a minor contaminating subset of IL-2Rα^+ pro-T cells

The functional role of the IL-2/IL-2Rβ interaction on pro-T cells indicated that IL-2 might be available in the thymus at an early developmental stage Indeed, analysis of IL-2 gene expression revealed that the levels of IL-2 mRNA found in freshly isolated pro-T cells were similar to those found in mitogen-activated T lymphocytes, whereas IL-2 transcripts were undetectable in resting peripheral T lymphocytes (Fig 3*a*)

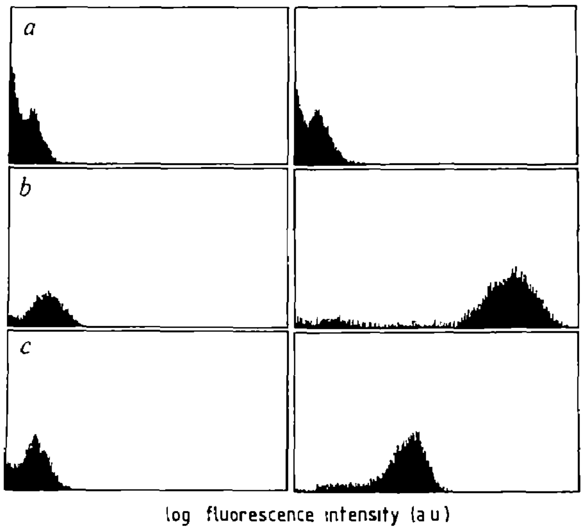

FIG 1 IL-2 induced expression of IL-2Rα in human pro-T cells Pro-T cells, either freshly isolated, *a*, or cultured during 8 days with 1 nM human rIL-2, *b*, or with 1 nM rIL-2 and a 300-fold molar excess of anti-IL-2Rα-monoclonal antibody, *c*, were analysed for the expression of IL-2Rα (right panel) Staining with an irrelevant antibody gives the background fluorescence (left panel)

METHODS Normal human thymocytes were obtained from thymus fragments removed during corrective cardiac surgery of patients of aged one month to three years Intrathymic stem cells, referred to as pro-T cells[22], were isolated by consecutive treatments with anti-CD1, -CD4, -CD8, -CD3 and -CD2 monoclonal antibodies plus rabbit complement (Beringwerke), as previously described[22] Recovered viable cells were treated again, in one step, with a cocktail of the indicated antibodies and incubated for 30 min at 4 °C with magnetic beads coated with affinity-purified sheep anti-mouse IgG (Dynabeads M-450, Dynal) This procedure allowed the isolation of a highly purified preparation of pro-T cells (>99% CD1$^-$2$^-$3$^-$4$^-$8$^-$) Pro-T cell cultures were set up in 24-well macroplates (Costar) (2 × 10^6 cells ml^{-1}) in RPMI-1640 medium (GIBCO) containing 10% FCS (GIBCO) and supplemented with either 1 nM human rIL-2 (Hoffman-La Roche) (cellular recovery ~500%) or with 1 nM rIL-2 plus a 300-fold molar excess of affinity-purified anti-IL-2Rα (H-108)[26] monoclonal antibody (cellular recovery ~300%) Either freshly isolated or cultured pro-T cells were washed twice in RPMI-1640 medium, incubated for 3 min at 4 °C in 0 15 M NaCl, 0 1 M glycine (pH 4) (glycine buffer) and washed again three times to remove bound anti-IL-2Rα antibody molecules Cells were then sequentially incubated with 10 μg ml^{-1} of biotin-conjugated anti-IL-2Rα (H-108) or irrelevant isotype-matching mouse monoclonal antibodies and phycoerythrin-conjugated streptavidin Quantitation of the surface staining of 5 × 10^4 viable cells was performed in an EPICS Profile flow cytometer (Coulter Electronics) The figure shows the results of one representative experiment out of four

Thus, IL-2 may be spontaneously produced by pro-T cells, allowing the acquisition of IL-2Rα '*in vivo*'

To characterize the functional status of the IL-2-induced IL-2Rα molecules, binding assays were performed with pro-T cells, after culture with 1 nM rIL-2 As compared with freshly isolated pro-T cells (Fig 2*a*), cultured pro-T cells showed a 20-fold increase in the expression of low affinity (IL-2Rα) receptors (21,200 sites per cell, $K_d \sim 19$ nM, Fig 2*d*) More importantly, a marked induction of high-affinity binding sites was also detected (980 sites per cell, $K_d \sim 12$ pM, Fig 2*d*) Binding of IL-2 to constitutive IL-2Rβ on pro-T cells leads to the activation of the IL-2Rα gene and results in the assembly of the high-affinity IL-2Rα/β heterodimer These results were confirmed at the protein level by chemical crosslinking performed under high-affinity conditions (with 150 pM ^{125}I-labelled IL-2) Two major IL-2-associated bands of $M_r \sim 90,000$ (90 K) and 70K, corresponding to IL-2Rβ and IL-2Rα, respectively, were detected in cultured pro-T cells (Fig 3*b*), whereas no crosslinked species were detected when pro-T cells were incubated with a 500-fold molar excess of either anti-IL-2Rα monoclonal antibody or unlabelled rIL-2 (Fig 3*b*)

The proliferative potential of pro-T cells was investigated in culture by using a broad concentration range of rIL-2 (1-10^5 pM), with or without saturating concentrations of anti-IL-

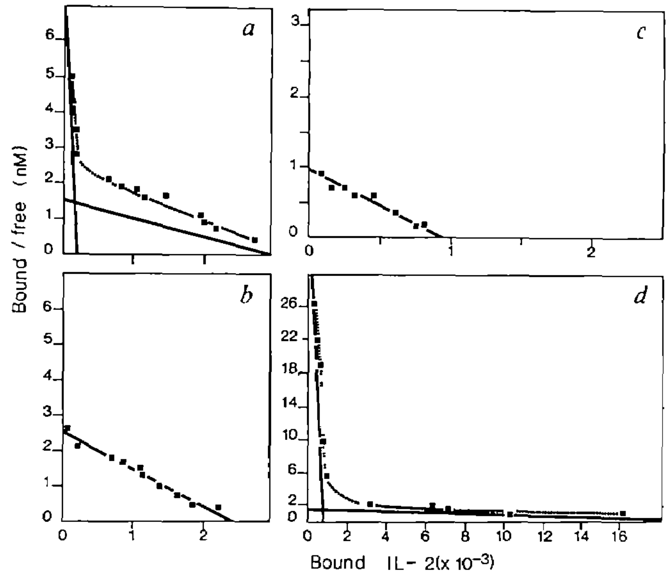

FIG 2 Quantitative analysis of IL-2 binding sites displayed by freshly isolated pro-T cells, resting peripheral T cells and IL-2 cultured pro-T cells IL-2 binding assays were performed in freshly isolated pro-T cells (*a*, *b*), in pro-T cells cultured with 1 nM rIL-2 for 8 days (*d*) and in resting peripheral T cells (*c*), either in the absence (*a*, *d*) or in the presence (*b*, *c*) of anti-IL-2Rα

METHODS Pro-T cells were obtained as described in Fig 1 legend, and highly purified resting peripheral T cells (96% CD2$^+$, <0 1% Tac$^+$, <0 5% CD16$^+$) were isolated from peripheral blood by nylon wool columns followed by treatment with anti-CD16 and anti-IL-2Rα antibodies and incubation with magnetics beads, as described in Fig 1 legend Aliquots of 2 × 10^7 cells were extensively washed and treated with glycine buffer as in Fig 1 to remove bound IL-2 molecules Cells (10^6) were then incubated with serial dilutions of ^{125}I-labelled human rIL-2 (1 pM–25 nM final concentration) (Amersham) for 1 h at 4 °C, in the absence or presence of a 500-fold molar excess of affinity-purified anti-IL-2Rα (H-108) antibody, as previously described[2,3] Specifically bound and free ^{125}I-labelled IL-2 were determined by solid scintillation counting The calculated values for the dissociation constant (K_d) and the number of binding sites per cell were derived by Scatchard computer analysis[27] of equilibrium binding data (solid lines) The dashed lines represent a computer-generated best fit to the experimental data The data were corrected for nonspecific binding of IL-2, determined in the presence of a 250-fold molar excess of unlabelled rIL-2, and for the loss of ligand binding activity incurred during the IL-2 labelling procedures The data are representative of three independent experiments

2Rα antibodies (3×10^{-7} M, Fig 4) In the absence of anti-IL-2Rα, IL-2 induced the proliferation of pro-T cells in a dose-dependent manner, maximal proliferation being achieved at doses of rIL-2 favouring intermediate-affinity binding (10 nM, Fig 4*a*) Also, blocking of IL-2Rα molecules did not affect cell proliferation at doses of rIL-2 high enough to saturate IL-2Rβ (<1 nM), whereas a significant inhibition was observed at low doses of rIL-2 (<500 pM), sufficient to bind to high-affinity IL-2Rα/β heterodimers (Fig 4*a*) By contrast, a fifteenfold lower concentration of rIL-2 was required to induce maximal proliferation of activated T cells expressing high-affinity IL-2R (100% Tac$^+$) and, therefore, a shift in the IL-2 dose-response curve was induced by anti-IL-2Rα Ten- to fifteenfold higher concentrations of IL-2, sufficient to saturate the IL-2Rβ, were then required to induce T-cell growth (Fig 4*c*) Similar inhibition patterns were observed for resting T lymphocytes (Fig 4*b*), supporting the reported IL-2-dependent induction of high-affinity receptors on these cells[14] The discrete proliferation observed in resting T cells when compared with pro-T cells (Fig 4) may reflect their lower expression of IL-2Rβ (900 compared with 2,300 sites per cell)

Taken together, these results indicate that both intermediate- and high-affinity IL-2R can be involved in the IL-2-promoted proliferation of pro-T cells, indicating that, before acquisition of IL-2Rα/β, IL-2Rβ alone can mediate signal transduction of IL-2 The observation that even without exogenous IL-2 supplementation, pro-T cells developed proliferative responses which can be blocked by anti-IL-2Rα monoclonal antibody, however, argues that the spontaneous and 'physiological' growth of these cells may be mediated mainly by the high-affinity form of the IL-2R Our data, therefore, provide evidence for the involvement of an IL-2-dependent autocrine pathway in the intrathymic development of mature T cells As previously proposed[23], such a nonspecific activation of polyclonal growth would operate selectively early in T-cell development, given the constitutive expression of mature IL-2 mRNA by pro-T cells In agreement with this, high levels of IL-2 transcripts have been detected in 15-day fetal thymocytes, whereas expression decreases dramatically by day 16 up until birth[24]

Although the activation signals inducing IL-2 gene expression within the thymus are as yet unknown, recent results indicate that cellular interactions involving thymic stromal components and production of lymphokines other than IL-2, such as IL-1, play an essential role in this process[25] Thus, IL-1 appears to induce a marked activation of IL-2 gene in precursor thymocytes (E Rothenberg, personal communication) In addition, we have observed that both IL-1 and IL-3 can regulate IL-2Rα expression on pro-T cells (unpublished data) Although the possibility that this induction results from endogenous IL-2 production in the culture cannot be ruled out, it seems likely that more than one cytokine pathway may allow the acquisition of an IL-2-responsive state which, in turn, would ensure polyclonal expansion of T-cell precursors and T-cell differentiation The autocrine behaviour that we propose occurs in T-cell differentiation could possibly be a common developmental strategy for other haemopoietic lineages □

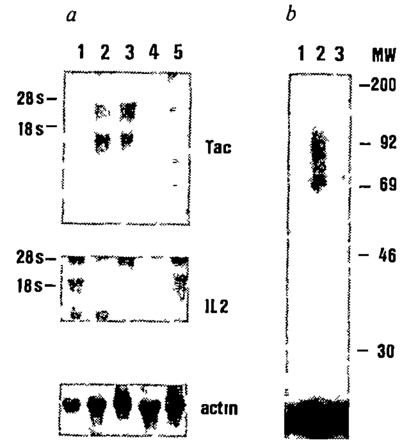

FIG 3 Constitutive expression of IL-2 transcripts in T-cell precursors and induction of IL-2Rα gene expression Acquisition of high-affinity IL-2Rα/β induced by IL-2/IL-2Rβ interactions *a*, Northern blot analysis of RNA obtained from freshly isolated pro-T cells (lane 1), phytohaemagglutinin-activated normal peripheral T cells (lane 2), pro-T cells cultured with 1 nM rIL-2 for 8 days (lane 3), JY B cells (lane 4) and resting peripheral T cells (lane 5) RNA (12 μg) was loaded on a formaldehyde-agarose gel, transferred to nylon membranes and hybridized with the ^{32}P-labelled (nick-translated) Tac-2A probe[28], the IL-2 probe[29], or an actin probe used as control, as previously described[22] *b*, Chemical crosslinking of ^{125}I-labelled IL-2 to IL-2-treated pro-T cells Pro-T cells, cultured for 8 days with 1 nM rIL-2 (10^7 cells) and washed with glycine buffer as described in Fig 2 legend, were incubated with ^{125}I-labelled human rIL-2 (150 pM) in the absence (lane 2) or presence of a 500-fold molar excess of either unlabelled rIL-2 (lane 1) or anti-IL-2Rα (H-108) monoclonal antibodies (lane 3) Disuccinimidyl suberate (Pierce) (0 3 nM) was used to covalently crosslink ^{125}I-labelled IL-2 to the surface of intact cells as previously described[9] Cells were solubilized in 1% SDS, 5% 2-mercaptoethanol sample buffer and analysed on 8% SDS-polyacrylamide gels Similar results were obtained in four independent experiments

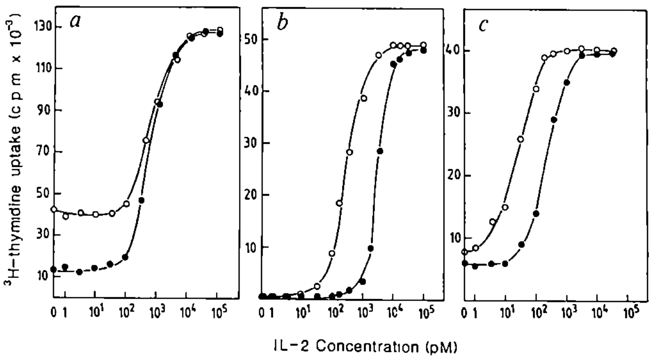

FIG 4 IL-2 induced proliferation of pro-T cells *a*, Pro-T cells, *b*, highly purified resting peripheral T cells, and *c*, phytohaemagglutinin-activated T cells were cultured in flat-bottomed 96-well microtitre plates (Costar) in RPM1-1640 medium at 10^6 cells ml^{-1} (*a*, *b*) or 10^5 cells ml^{-1} (*c*) with $3\,0\times10^{-7}$ M normal mouse affinity-purified IgG (○) or anti-IL-2Rα (H-108) antibody (●), in the presence of different concentrations of rIL-2 (1–10^5 pM) Proliferative responses were analysed by [^{3}H]thymidine incorporation at day 5 of culture, after addition of 1 μCi per well of [^{3}H]thymidine (Amersham) for the last 18 h Each value represents the mean of triplicate cultures Standard deviations were ≤10%

A glycophospholipid anchor is required for Qa-2-mediated T cell activation

Peter J. Robinson, Margaret Millrain, Jane Antoniou*, Elizabeth Simpson & Andrew L. Mellor*

Transplantation Biology Section, Clinical Research Centre, Watford Road, Harrow, Middlesex HA1 3UJ, UK
* Division of Immunology, National Institute for Medical Research, The Ridgeway, Mill Hill, UK

A NUMBER of lymphocyte surface proteins are anchored in the cell membrane by glycophosphatidyl inositol (known as GPI) linkages instead of hydrophobic protein domains[1,2] Treatment of mouse T lymphocytes with antibodies specific for two such proteins, Thy-1 and Ly-6, are known to induce proliferation[3,4] We have found that antibodies specific for Qa-2, a GPI-anchored class I histocompatibility antigen[5], can also activate mouse T cells. To determine whether the GPI-anchor is important for this pathway of cell activation, we produced transgenic mice expressing either normal GPI-anchored Qa-2, or Qa-2 molecules with a membrane-spanning protein domain derived from H-2 Our studies show that only lymphocytes from transgenic mice carrying GPI-anchored forms of Qa-2 can be activated *in vitro* by Qa-2-specific antibodies. We also show that transgenic mouse T cells expressing a GPI-anchored form of H-2D^b can be activated by anti-H-2D^b antibodies These results strongly indicate that the GPI-anchor is critical for this pathway of T cell activation

Activation of T cells is normally the result of binding of antigen receptors to antigenic peptides presented in association with major histocompatibility antigens A number of other T-cell membrane proteins (for example, CD2, CD3 and CD28) can also induce activation in response to specific antibodies[6-8] These antibodies may therefore mimic the binding of signalling molecules to their natural ligands Molecules such as CD2 are transmembrane proteins that require a cytoplasmic domain to function in signalling[9] Some GPI-anchored membrane proteins, such as Thy-1, have also been shown to act as signalling molecules, despite the fact that the fatty acid anchoring group appears to associate with only one face of the lipid bilayer[2,10] This indicates the existence of a second type of transmembrane signal delivery pathway involving GPI-anchors[11]

In mice, the class I, H-2 K, D and L major histocompatibility antigens are transmembrane glycoproteins that are thought to present processed endogenous antigenic fragments to receptors on T cells Antibodies against H-2 are not normally mitogenic for T cells but antibodies specific for Qa-2, a GPI-anchored class I molecule[5], are Purified T cells from C57BL/10, Qa-2$^+$, mice were stimulated to divide by three Qa-2 specific monoclonal antibodies T cells from BALB/cJ mice, which express fewer Qa-2 molecules, could also be activated under these conditions Anti-immunoglobulin antibody and phorbol myristate acetate (PMA), an activator of protein kinase C, were both required for cell division to occur Specificity for Qa-2 could be demonstrated by examining the proliferative responses of T cells from recombinant mouse strains B6 K1 and B6 K2, which differ only in the *Q* region[12] of the major histocompatibility complex T cells from B6 K2 mice, which express Qa-2, could be activated by Qa-2 specific antibodies, but T cells from B6 K1 mice, which lack the antigen, could not (Table 1) Both types of T cells, however, respond equally well to Thy-1 specific antibodies

To determine whether the GPI membrane anchor is required for the triggering of T cells by Qa-2 specific antibodies, we constructed hybrid class I genes by recombining segments of $Q9^b$ or $Q7^b$, which both encode GPI-anchored Qa-2 molecules[13-15], with corresponding regions of $H\text{-}2D^b$ The products of hybrid genes *QD1* and *QD3* are shown in Fig 1 A GPI-anchored Qa-2 molecule is encoded by *QD1*, and *QD3* encodes a variant form of Qa-2 which spans the cell membrane using a transmembrane segment derived from H-2D^b Transgenic mice were derived by introducing these constructs into fertilized oocytes from CBA/Ca mice, which lack the genes for Qa-2 As shown in Fig 2, spleen cells from both CBA/Ca QD1 and CBA/Ca QD3 transgenic mice expressed molecules reactive with anti-Qa-2 antibodies QD1 molecules could be removed from cell membranes by treatment with phosphatidylinositol-specific phospholipase C (PtdIns-PLC), indicating the presence of a GPI anchor, but QD3 molecules were completely resistant to the enzyme

To confirm that QD3 molecules have a transmembrane orientation, we treated microsomal membranes from biosynthetically labelled CBA/Ca QD3 spleen cells with proteinase K Cytoplasmic domains of transmembrane proteins exposed on the microsomal surface immediately after synthesis are removed by the enzyme[16] Gel electrophoresis shows that QD3 molecules were reduced in relative molecular mass by ~3,000 following proteinase K treatment, consistent with removal of the H-2D^b-derived cytoplasmic domain[16] By contrast, the size of QD1 was unchanged (data not shown) This confirms that QD3 spans the membrane Both QD1 and QD3 were found to be associated with beta-2 microglobulin, as are Qa-2 and H-2D^b (data not shown)

The proliferative responses of T cells from CBA/Ca, CBA/Ca QD1 and CBA/Ca QD3 mice treated with Thy-1 or

TABLE 1 Proliferation of mouse T cells in response to Qa-2 specific antibodies

Cells	Antibody	Specificity	[^{3}H]thymidine incorporation (c p m)
C57BL/10	None	—	600
	Qa-m2	Qa-2	48,000
	Qa-m7	Qa-2	67,000
	D3 262	Qa-2	14,000
	H142 45	H-2K^b, D^b	<600
	B22 249	H-2D^b	<600
	K9 136	H-2K^b	<600
BALB/c	None	—	3,400
	Qa-m2	Qa-2	56,000
	KT16	Thy-1	104,000
B6 K1	Qa-m2	Qa-2	300
	KT16	Thy-1	66,000
B6 K2	Qa-m2	Qa-2	23,900
	KT16	Thy-1	68,000

T lymphocytes were isolated from mouse spleens by nylon wool fractionation followed by absorption to anti-immunoglobulin coated dishes Cells were then incubated with stimulatory antibodies at 1 μg ml^{-1} for 30 min at 25 °C, washed then cultured for 48 h in 96-well costar plates at 5×10^5 cells per well in the presence of rabbit anti-mouse immunoglobulin F(ab')$_2$ fragments (5 μg ml^{-1}) and PMA (50 ng ml^{-1}) Cell cultures were pulsed with [^{3}H]thymidine (1 μCi, for 2 h), collected and counted

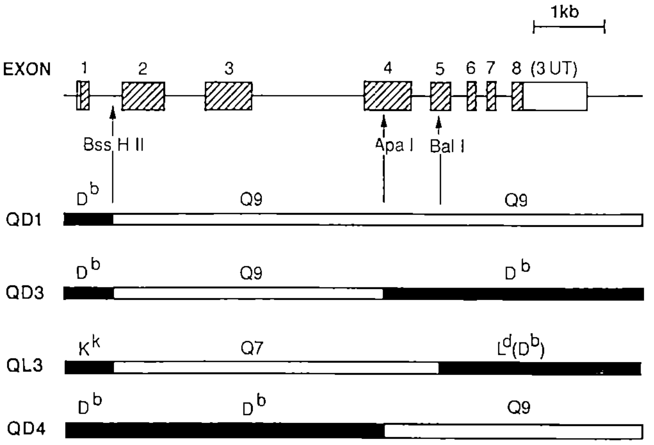

FIG 1 Construction of *H-2/Qa-2* hybrid genes Subclones of *H-2D^b*, *Q7^b* and *Q9^b* genes were recombined at the *Bss*HII, *Apa*I and *Bal*I sites indicated to construct the hybrid genes Plasmid sequences were removed before injection into pronuclei of fertilized CBA/Ca mouse embryos using standard procedures Transgenic *QD1*, *QD3*, and *QL3* mice were identified by hybridization of DNA from tail biopsy to a probe for the *Q9* large intron (between exons 3 and 4) *QD4* mice were identified using a 0 5 kb *Bam*HI fragment of *H-2D^b* from the 5′ flanking region[20] UT, untranslated

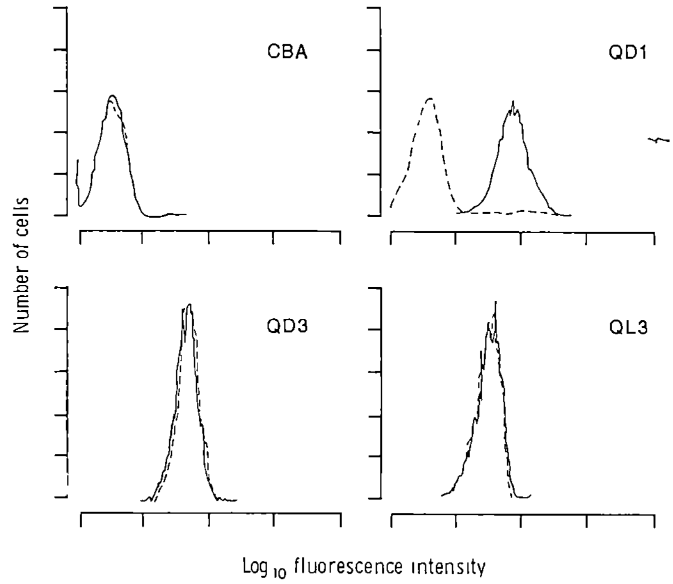

FIG 2 Flow cytometry of hybrid class I molecules on transgenic T cells T cells from transgenic mouse spleens were gated using biotinylated L3T4 and Ly-2 specific antibodies which were developed with streptavidin phycoerythrin Transgene products on T cells were stained using Qa-m2 antibody and rabbit antimouse immunoglobulin conjugated to fluorescein isothocyanate Solid lines show untreated cells, broken lines show cells after treatment with PtdIns-PLC before addition of antibody Conjugate-only controls were indistinguishable from CBA/Ca profiles and therefore are not shown

Qa-2 specific antibodies are shown in Table 2 Antibodies specific for Qa-2 were mitogenic for T cells from CBA/Ca QD1, but not CBA/Ca or CBA/Ca QD3 mice Proliferation of CBA/Ca QD1 cells was abrogated by pretreatment with PtdIns-PLC T cells from all three mouse lines responded well to Thy-1 specific antibodies, confirming that this activation pathway is not distorted by the presence of the transgene or its product These results suggest that binding of anti-Qa-2 antibodies is only mitogenic for T cells if the target antigen is anchored in the membrane with a GPI linkage

In addition to their membrane anchors, QD1 and QD3 differ by eight amino acids in their membrane-proximal alpha-3 protein domains To investigate whether T cells expressing membrane-spanning class I molecules with extracellular domains entirely of Qa-2 origin would proliferate in response to anti-Qa-2 antibodies, we produced transgenic mice expressing another construct, *QL3* As shown in Fig 1, the entire extracellular section of QL3 is derived from Qa-2 The remainder of the molecule, including part of the membrane-spanning segment and the cytoplasmic domain, is from H-2L^d QL3 molecules were stably expressed as transmembrane glycoproteins on the surface of transgenic T cells (Fig 2), despite the presence of an intramembrane aspartic acid residue, encoded by *Q7^b*, which was previously shown to be important for the addition of the GPI anchor[17] T cells from CBA/Ca QL3 and CBA/Ca QD3 transgenic mice behaved similarly in the proliferation assay Both gave a strong proliferative response to anti Thy-1 but no response to anti-Qa-2 antibodies As the entire extracellular portions of QD1 and QL3 differ by only a single amino acid at position 173 (alpha-2 domain) owing to a single base change between *Q7* and *Q9* (ref 15), this strongly suggests that it is the GPI anchor that endows QD1 with the ability to deliver activation signals

If GPI membrane anchors can confer transmembrane signalling capability on membrane proteins it should be possible to create new signal delivery structures by attaching phospholipid anchors to normally non-mitogenic molecules To test this we produced one further transgenic mouse line, CBA/Ca QD4, which expresses a GPI-anchored derivative of the H-2D^b

TABLE 2 Response of transgenic mouse T cells to class I-specific antibodies

Experiment 1 Antibody	Specificity	[^{3}H]Thymidine incorporation (c p m) CBA/Ca	QD1	QD3
–	–	260 (260)	340 (540)	300 (270)
KT16	Thy-1	35,400 (6,400)	73,000 (34,200)	95,400 (11,700)
Qa-m2	Qa-2	170 (70)	28,670 (147)	80 (90)
Experiment 2		C57BL/10	QL3	QD4
–	–	ND	2,400	6,800
KT16	Thy-1	124,600 (40,800)	116,000 (152,000)	70,100 (34,000)
Qa-m2	Qa-2	29,800 (7,300)	2,200 (2,100)	5,100 (ND)
141 30	H-2D^b	5,100 (6,800)	5,700 (ND)	25,400 (10,300)

Conditions as for Table 1 In parentheses, cells were pretreated with 0 1U ml^{-1} *Bacillus thuringiensis* PtdIns-PLC (1 h, 37 °C) and washed before adding stimulatory antibody molecule (Fig 1) We found that T cells from these animals could be activated by antibodies against H-2D^b (Table 2) The antibody used, H141 30, is specific for the two outermost protein domains of H-2D^b (ref 18) This was demonststrated by a lack of reactivity with cells carrying H-2L^d (ref 18), which has an identical sequence to H-2D^b in the alpha-3 domain Antibody H141 30 does not cross-react with Qa-2, as indicated by its lack of reactivity with CBA/Ca QD1 spleen cells (data not shown) and did not cause proliferation of C57BL/10 T cells, which express conventional H-2D^b molecules (Table 2)

These activation data can best be explained by involvement of phospholipid membrane anchors in the process of transmembrane signalling and thus constitute direct evidence of a biological function associated with a GPI membrane anchor Other potential attributes of GPI linkages, such as increased lateral mobility of proteins in the plane of the membrane and their potential for selective release by phospholipases[1,2], have not yet been shown to have functional importance By contrast, there is evidence suggesting the involvement of GPI anchors in cell activation[11] First, treatment of lymphocytes with PtdIns-PLC reduces their response to mitogens[5] Second, T cell lines defective in anchor biosynthesis show reduced lymphokine production when stimulated with antigen[19] The precise mechanism by which GPI anchors participate in cell triggering phenomena is still unclear, but their involvement in the activation of T lymphocytes suggests that they may be important for the regulation of cell proliferation during the immune response ☐

INOSITOL 1,4,5-trisphosphate (Ins (1,4,5)P_3), a second messenger molecule involved in actions of neurotransmitters, hormones and growth factors, releases calcium from vesicular non-mitochondrial intracellular stores[1] An Ins(1,4,5)P_3 binding protein, purified from brain membranes[2], has been shown to be phosphorylated by cyclic-AMP-dependent protein kinase[3] and localized by immunohistochemical techniques to intracellular particles associated with the endoplasmic reticulum[4] Although the specificity of the Ins(1,4,5)P_3 binding protein for inositol phosphates and the high affinity of the protein for Ins(1,4,5)P_3 indicate that it is a physiological Ins(1,4,5)P_3 receptor mediating calcium release, direct evidence for this has been difficult to obtain Also, it is unclear whether a single protein mediates both the recognition of Ins(1,4,5)P_3 and calcium transport or whether these two functions involve two or more distinct proteins. In the present study we report reconstitution of the purified Ins(1,4,5)P_3 binding protein into lipid vesicles We show that Ins(1,4,5)P_3 and other inositol phosphates stimulate calcium flux in the reconstituted vesicles with potencies and specificities that match the calcium releasing actions of Ins(1,4,5)P_3 These results indicate that the purified Ins(1,4,5)P_3 binding protein is a physiological receptor responsible for calcium release

The Ins(1,4,5)P_3 receptor protein was solubilized using CHAPS as a detergent, rather than Triton X-100 which has been used previously[2], because Triton detergent is not compatible with the dialysis technique of vesicle reconstitution[5,6] The Ins(1,4,5)P_3 receptor protein was purified as previously described[2] with minor modifications (see Fig 1) In the reconstitution experiments purified Ins(1,4,5)P_3 receptor protein was added to a mixture of CHAPS, solubilized phosphatidylcholine and phosphatidylserine, and the mixed micelles of protein and lipid were dialysed for 48 hr against a 1,000-fold excess of buffer To determine whether the Ins(1,4,5)P_3 binding protein was incorporated into vesicles, we fractionated the vesicles on a continuous sucrose gradient and monitored [^{3}H]Ins(1,4,5)P_3 binding as well as levels of [^{14}C]phosphatidylcholine, which we used as a marker for the lipid vesicles (Fig 1*b*) The [^{3}H] Ins(1,4,5)P_3 binding activity and [^{14}C]phosphatidylcholine co-migrated on the gradient and nearly 100% of the binding activity was recovered Total protein concentration also co-migrated with the peak of [^{3}H]Ins(1,4,5)P_3 binding activity (data not shown) Pure Ins(1,4,5)P_3 binding protein, dialysed in the absence of lipid, appeared to aggregate as it migrated to the densest portion of the gradient (data not shown) Lipid vesicles without receptor protein appeared slightly less dense than the protein containing vesicles (data not shown) Analysis of protein within the vesicles by SDS-PAGE revealed a single band with a relative molecular mass of 260,000 (260K) (Fig 1*a*), the same as purified Ins(1,4,5)P_3 receptor protein not incorporated into vesicles[2] Thus, the reconstitution procedure results in the incorporation of Ins(1,4,5)P_3 binding protein into the vesicles with no change in molecular weight, and the protein retains its ability to bind Ins(1,4,5)P_3

The properties of [^{3}H]Ins(1,4,5)P_3 binding in the reconstituted vesicles were essentially the same as those of the purified unreconstituted protein[2] Unlabelled Ins(1,4,5)P_3 inhibited [^{3}H]Ins(1,4,5)P_3 binding 50% at ~40nM (Fig 2) Of a variety of inositol phosphates examined, Ins(1,4,5)P_3 was the most potent inhibitor of binding with Ins(2,4,5)P_3 being the next potent Both Ins(1,3,4)P_3 and Ins(1,3,4,5)P_4 were much less potent inhibitors of binding, whereas other inositol phosphates examined were essentially inactive (Table 1) Heparin, a known inhibitor of Ins(1,4,5)P_3 binding[7] and Ins(1,4,5)P_3-mediated

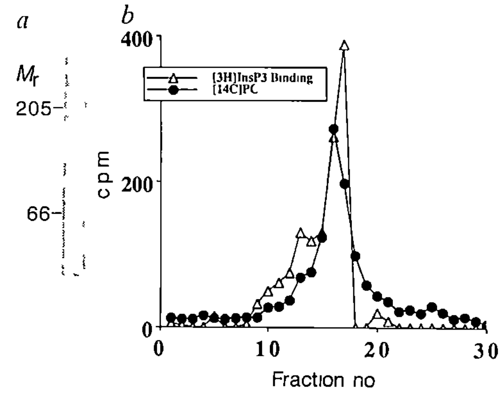

FIG 1 Reconstitution of purified Ins(1,4,5)P_3 receptor protein *a*, SDS-PAGE analysis of protein in reconstituted lipid vesicles (7 5% gel, Coomassie Brilliant Blue stain) *b*, Disposition of specific [^{3}H]Ins(1,4,5)P_3 (open triangles) binding in continuous sucrose gradient (5–20%) fractionation of reconstituted proteoliposomes Fraction number 1 corresponds to 20% sucrose or the bottom of the gradient, whereas fraction number 30 is 5% sucrose at the top of the gradient The [^{14}C]Phosphatidylcholine (PC, closed circles) was used as a tracer for the lipid vesicles Nonspecific [^{3}H]Ins(1,4,5)P_3 binding was measured in the presence of 1 μM Ins (1,4,5)P_3 This experiment was performed three times with the same results Binding was determined in duplicate or triplicate with replicates varying <10%

METHODS Ins(1,4,5)P_3 receptor was purified as described[2] with the following modifications CHAPS (1%, Sigma) was used as the detergent to allow dialysis for reconstitution, and the receptor was purified using only two affinity column chromatography steps[2] Partially purified receptor was obtained by fractionating CHAPS solubilized proteins on Heparin agarose (Sigma, Type II) as described[2] The purified receptor was obtained by fractionating the proteins which elute from heparin agarose on concanavalin sepharose[2] The reconstitution strategy was based on a previously described procedure used for the nicotinic acetylcholine receptor[6] Solubilized liposomes were prepared by sonicating (for 12–20 min in a cylindrical bath sonicator) a mixture of phosphatidylcholine (in the presence or absence of tracer amounts of [^{14}C] phosphatidylcholine) and phosphatidylserine (Avanti Polar Lipids) at a ratio of 3 1, and a lipid concentration of 40 mg ml^{-1} and in a buffer (buffer A) containing 50 mM NaCl, 50 mM KCl and 20 mM Tris-HCl (pH 7 4, 25 °C) Following sonication the lipid concentration was reduced to 20 mg ml^{-1} by adding an equal volume of buffer A and CHAPS was added to bring the final detergent concentrations to 1% This lipid mixture was then mixed with purified Ins(1 4,5)P_3 receptor (100 μg ml^{-1} protein) or partially purified (400 μg ml^{-1}) at a ratio of 1 1 After incubation on ice for 20 min, the mixture was dialysed (molecular mass cutoff, 10,000) against a 1,000-fold excess of buffer A supplemented with 1 mM EDTA, 1 mM EGTA and 2 mM 2-mercaptoethanol The buffer was changed every 8 h for 48 h to effect detergent removal and vesicle formation These vesicles were then loaded onto a 5–20% continuous sucrose gradient (30 ml) and centrifuged overnight (SW 28, 20,000 r p m (140,000*g*) Beckman Ultracentrifuge) Fractions (1 ml) were collected, [^{14}C]phosphatidylcholine content and [^{3}H]Ins(1,4,5)P_3 binding were measured Protein concentration was determined by the method of Bradford[22], and SDS-PAGE was by the method of Laemmli[23]

calcium release[8–13], completely inhibited binding at 100 μg ml^{-1} (Table 1) As previously reported for the purified, unreconstituted Ins(1,4,5)P_3 binding protein[2], calcium (1 mM) had no effect on [^{3}H]Ins(1,4,5)P_3 binding—which was markedly influenced by pH, more than doubling as pH was increased from 7 4 to 8 8 (data not shown)

To monitor calcium flux, reconstituted vesicles were incubated with $^{45}Ca^{2+}$ in the presence or absence of various concentrations of Ins(1,4,5)P_3 or other inositol phosphates (Figs 2,3, Table 1) At 10 μM Ins(1,4,5)P_3 the rate of $^{45}Ca^{2+}$ flux was stimulated at least fivefold, being half maximal within 4 s and complete within 10 s (Fig 3) The very rapid kinetics of Ins(1,4,5)P_3-stimulated $^{45}Ca^{2+}$ influx would be expected for ion channels reconstituted in small unilamellar liposomes[6] Half maximal and maximal Ins(1,4,5)P_3-stimulated $^{45}Ca^{2+}$ influx required ~40 nM and 1 μM Ins(1,4,5)P_3, respectively, very similar to corresponding potencies for inhibiting [^{3}H]Ins(1,4,5)P_3 binding (Fig 2) The relative effects of other inositol phosphates on $^{45}Ca^{2+}$ flux also resembled their influences on [^{3}H]Ins(1,4,5)P_3 binding, with Ins(1,4,5)P_3 being most potent and Ins(2,4,5)P_3 the only other inositol phosphate with activity (Table 1) These effects resemble the relative calcium-releasing potencies of inositol phosphates in several systems[14–16] Also, the relative potencies of the inositol phosphates in mediating $^{45}Ca^{2+}$ release from cerebellar microsomes were the same as in the reconstituted vesicles (data not shown) Interestingly, whereas Ins(1,3,4)P_3 and Ins(1,3,4,5)P_4, at concentrations of 10 and 20 μM respectively, produced significant inhibition of [^{3}H]Ins(1,4,5)P_3 binding, they did not elicit a calcium flux (Table 1) Whether these results indicate that at those concentrations these substances are Ins(1,4,5)P_3 receptor antagonists is not clear Heparin (100 μg ml^{-1}) completely blocked the ability of Ins(1,4,5)P_3 (1 μM) to stimulate a $^{45}Ca^{2+}$ flux (Table 1) with no effect on $^{45}Ca^{2+}$ flux in the absence of Ins (1,4,5)P_3

Although in these experiments we examined the effects of inositol phosphates on the influx of $^{45}Ca^{2+}$ into reconstituted vesicles, in other experiments we have shown similar effects on $^{45}Ca^{2+}$ release from reconstituted vesicles preloaded with $^{45}Ca^{2+}$ Ins(1,4,5)P_3 doses of 10 μM or 1 μM released, with rapid kinetics, the $^{45}Ca^{2+}$ from the inside of vesicles preloaded by freeze thaw (see Fig 3 legend) When the partially purified preparations of the receptor (see Fig 1 legend) were reconstituted in parallel with the purified receptor, the specific activity of [^{3}H]Ins(1,4,5)P_3 binding increased 9 3-fold after the second affinity chromatography step, whereas the specific activity of Ins(1,4,5)P_3-mediated calcium flux increased 10 3-fold In

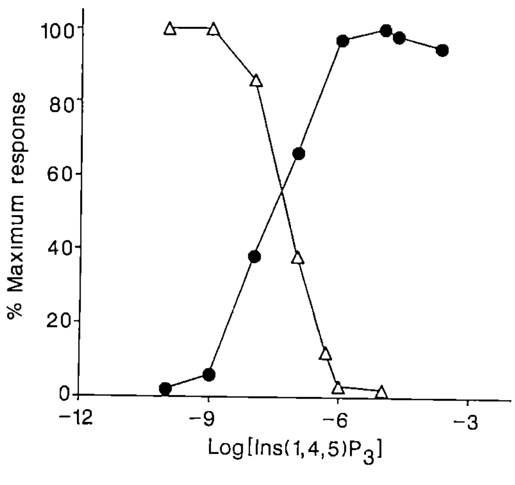

FIG 2 Concentration-response relationships for Ins(1,4,5)P_3 inhibition of [^{3}H]Ins(1,4,5)P_3 binding (△) and stimulation of $^{45}Ca^{2+}$ influx into vesicles (●) reconstituted from purified Ins(1,4,5)P_3 receptor protein Calcium flux was measured as described in the legend to Fig 3, and the incubation time for calcium flux was 10 s This experiment has been performed four times with essentially the same results Measurements were made in triplicate or quadruplicate with replicates varying <10%

experiments using lipid vesicles without incorporated Ins(1,4,5)P_3 receptor protein, no effects of inositol phosphates on the $^{45}Ca^{2+}$ flux were detected Also, reconstitution of protein from column fractions containing no binding activity resulted in vesicles that had no Ins(1,4,5)P_3-stimulated $^{45}Ca^{2+}$ transport To demonstrate that the intact vesicle structure is required for Ins(1,4,5)P_3 effects on calcium flux, we solubilized reconstituted vesicles with CHAPS (1%) and were no longer able to detect Ins(1,4,5)P_3-stimulated $^{45}Ca^{2+}$ flux In addition we examined whether the $^{45}Ca^{2+}$ accumulated in the reconstituted vesicles after Ins(1,4,5)P_3 stimulation could be released by ionophores We therefore collected the vesicles after passing them over the Dowez column, incubated them in the presence and absence of the calcium ionophore A23187 and then passed them over a second Dowex column All of the $^{45}Ca^{2+}$ accumulated after Ins(1,4,5)P_3 stimulation was released by the ionophore

Our ability to reconstitute Ins(1,4,5)P_3-stimulated calcium flux into lipid vesicles containing purified Ins(1,4,5)P_3 binding protein establishes that this protein is a physiological receptor mediating Ins(1,4,5)P_3 effects on calcium release The close correlation between potency of inositol phosphates to influence ligand binding and calcium flux supports this conclusion Our findings also establish that a single protein mediates both recognition of Ins(1,4,5)P_3 and the stimulation of calcium flux In this way the Ins(1,4,5)P_3 receptor resembles neurotransmitter-gated ion channels, such as the nicotinic acetylcholine[6], GABA (γ-aminobutyric acid)-benzodiazepine[17], and glycine[17] receptors, in which a single protein-complex contains recognition sites both for the neurotransmitter and associated ion channels These neurotransmitter receptors are comprised of several distinct subunits, whereas the Ins(1,4,5)P_3 receptor seems to be a tetramer of four identical subunits[2] The neurotransmitter receptors are integral proteins of the plasma membrane with recognition sites on the extracellular surface, whereas the Ins(1,4,5)P_3 receptor is a novel intracellular receptor with the recognition site for Ins(1,4,5)P_3 on the cytoplasmic side In this way the Ins(1,4,5)P_3 receptor resembles the recently characterized[18-20] and cloned[21] ryanodine receptor, which mediates calcium flux from the sarcoplasmic reticulum of skeletal muscle The Ins(1,4,5)P_3 receptor also resembles the ryanodine receptor in having a high relative molecular mass, and a similar proposed subunit structure and chromatographic behaviour[18-21] It is likely, therefore, that these two receptors are members of a new class of intracellular ligand-gated ion channels ☐

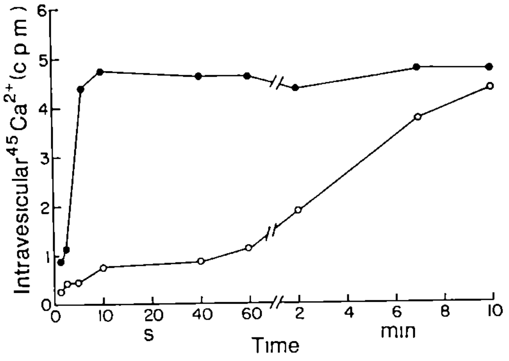

FIG 3 Time course of $^{45}Ca^{2+}$ flux in vesicles reconstituted with purified Ins(1,4,5)P_3 receptor Open symbols, accumulation of $^{45}Ca^{2+}$ in reconstituted vesicles in the absence of any agonist, closed symbols, $^{45}Ca^{2+}$ accumulated in the presence of 10 μM Ins(1,4,5)P_3 Data are expressed as c p m (×1,000) This experiment has been replicated three times with similar results Measurements were made in duplicate or triplicate with replicates varying <10%

METHODS Following reconstitution of the purified Ins(1,4,5)P_3 receptor as described in the legend to Fig 1, vesicles were dialysed overnight in buffer A supplemented with 2 mM 2-mercaptoethanol to remove the calcium chelators which interfere with calcium flux measurements and to bring the final calcium concentration to nominally free levels of ~10 μM free calcium as measured by a calcium sensitive macroelectrode Calcium flux was determined using tracer amounts of $^{45}Ca^{2+}$ and cation exchange chromatography Calcium influx was measured by incubating 85 μl of reconstituted vesicles with 2 μCi $^{45}Ca^{2+}$ in the presence or absence of 10 μM Ins(1,4,5)P_3 The final reaction volume was 100 μl After incubation for the indicated times, the flux reaction was stopped with a threefold excess of buffer A supplemented with 0 3 mM $CaCl_2$, 5 mM $MgSO_4$, 1 mM $CdCl_2$ and 100 μg ml^{-1} heparin (Sigma) (Stop buffer) This 400 μl mixture of vesicles and stop buffer was immediately loaded onto a 3 ml column of Tris-Dowez (Sigma, Dowez 50-W X-8, pH 8 0) which had been equilibrated with buffer containing 200 mM sucrose, 20 mM Tris (pH 7 4, 25 °C) and 0 3% BSA The column was immediately washed with 3 5 ml of the same buffer (without BSA) to wash the vesicles and the intravesicular $^{45}Ca^{2+}$ through the column The $^{45}Ca^{2+}$ content of the vesicles was determined by liquid scintillation spectrometry In some experiments, however, following the removal of extravesicular calcium by the Dowez column, the vesicles were immediately incubated in 3 5 ml of the sucrose containing buffer in the presence or absence of 10 μM A23187, a calcium selective ionophore After a 10 min incubation at 22 °C, the vesicles were reloaded onto (and washed through) a second Dowex column (6 ml column volume) to determine the selective releasibility of the accumulated calcium For efflux measurements vesicles were loaded with $^{45}Ca^{2+}$ by rapid freeze thaw After freeze thaw, vesicles were diluted fivefold into buffer A in the presence or absence of 10 μM Ins(1,4,5)P_3 After a 10 s incubation at 22 °C the flux reaction was stopped and the intravesicular $^{45}Ca^{2+}$ content was determined as described above

TABLE 1 [^{3}H]Ins(1,4,5)P_3 binding and Ins(1,4,5)P_3-stimulated $^{45}Ca^{2+}$ flux

Compound	Concentration (μM)	% Inhibition of [^{3}H]Ins(1,4,5)P_3 binding	% Stimulation of $^{45}Ca^{2+}$ flux
Ins(1,4,5)P_3	1	100	97
Ins(1,3,4)P_3	10	40	0
Ins(2,4,5)P_3	2	72	52
Ins(2)P	5	3	0
Ins(4)P	5	0	0
Ins(1,4)P_2	10	5	0
Ins(1,3,4,5)P_4	20	62	0
InsP_5	10	12	0
InsP_6	10	15	0
Heparin	100 μg ml^{-1}	100	0
Ins(1,4,5)P_3 +heparin	1 100 μg ml^{-1}	—	3

Calcium flux and [^{3}H]Ins(1,4,5)P_3 binding were determined as described in the legends to Figs 1 and 2 Flux measurements were made after a 10 s incubation as in Fig 3 These experiments have been performed three times in triplicate or quadruplicate with replicates varying by <15%

THE rapid removal of Ca^{2+} ions from the cytosol, necessary for the efficient relaxation of cardiac muscle cells, is performed by the Ca^{2+}-pumping ATPase of the sarcoplasmic reticulum The calcium pump is activated by cyclic AMP- and calmodulin-dependent phosphorylation of phospholamban, an integral membrane protein of the sarcoplasmic reticulum. Using a heterobifunctional crosslinking agent which can be cleaved and photoactivated, we provide evidence for a direct interaction between the two proteins Only the non-phosphorylated form of phospholamban interacts with the ATPase, demonstrating that phospholamban is an endogenous inhibitor that is removed from the ATPase by phosphorylation Non-phosphorylated phospholamban interacts only with the calcium-free conformation of the ATPase and is released when it is converted to the calcium-bound state We localized the site of interaction to a single peptide isolated after cyanogen bromide cleavage of the ATPase The peptide derives from a domain just C-terminal to the aspartyl phosphate of the active site. This domain is unique to ATPases of the sarcoplasmic reticulum in that it has no homology with any other phosphorylation-type ion pump The domain occurs in both slow- and fast-twitch isoforms of the ATPase, even though phospholamban is not expressed in fast-twitch muscles

Phospholamban (PLN) is a complex of five identical amphipathic peptides of relative molecular mass (M_r) ~6,000 (ref 1) In its hydrophilic domain each monomer contains adjacent serine and threonine residues that can be selectively phosphorylated by the cAMP-dependent and calmodulin-dependent kinases respectively[2] Phosphorylation of PLN is important in the mechanical response of cardiac muscle to stimulation by beta-agonists[3,4] We isolated phospholamban oligomer[5] and conjugated the ε-amino group of its single lysine residue, situated near the N-terminus in the hydrophilic domain, to the *N*-oxysuccinimide moiety of the heterobifunctional Denny-Jaffe crosslinking reagent[6] to form a stable amide linkage When conjugated with the Denny-Jaffe reagent, PLN remains oligomeric The reagent contains a cleavable distal portion carrying a photoactivatable aryl azide and a radioactive ^{125}I label It has been postulated that PLN, which is present in roughly stoichiometric amounts with the calcium pump (that is, one monomer per pump unit), interacts directly with the enzyme to induce a conformational change in it Light activation of conjugated PLN incubated with purified cardiac sarcoplasmic reticulum (SR) ATPase resulted in the formation of a complex (Fig 1, lane 3) But when PLN was pre-phosphorylated by the cAMP-dependent kinase, or when Ca^{2+} ions were added to the incubation mixture, there was no crosslinking with the ATPase (Fig 1, lanes 1, 2 and 4) Complex formation therefore occurs only when PLN is in the unphosphorylated state Experiments using reconstitution techniques[7], monoclonal antibodies against PLN[8] or controlled tryptic digestion of PLN[9] have indicated that PLN is an inhibitor of the calcium pump and that phosphorylation removes this inhibition, a suggestion that is now strongly supported by our result

Addition of 100 μM Ca^{2+} completely inhibits complex formation between the two proteins (Fig 1) When Ca^{2+} ions bind to high-affinity sites[10], the ATPase undergoes a large conformational change to assume the E_1 conformation, which can then be phosphorylated by ATP during the calcium transport cycle[11] We investigated whether inhibition of the PLN interaction by calcium resulted from conversion of the ATPase into the E_1 state by studying the calcium dependence of the hydrolytic activity of the pump in parallel with labelling experiments The hydrolytic activity can be taken as an indicator of the saturation level of the high-affinity Ca^{2+}-binding sites[11] Figure 2 shows that the activation of the pump by Ca^{2+} is inversely correlated with its ability to interact with PLN, so only the E_2 (Ca^{2+}-free) conformation of the ATPase can bind PLN Interaction with non-phosphorylated PLN therefore shifts the equilibrium of the pump in favour of the E_2 form, slowing down the $E_2 \rightarrow E_1$ conversion and raising the apparent K_m for calcium of the enzyme This would explain earlier observations on the binding kinetics of Ca^{2+} to the cardiac ATPase PLN phosphorylation, which results in the removal of PLN from its binding site on the pump, was shown to increase the rate of binding of Ca^{2+} ions[12] and the apparent affinity for calcium of the ATPase[13,14] Changes in the electrostatic properties of the SR membrane during PLN phosphorylation also contribute to the increased calcium affinity of the ATPase[15]

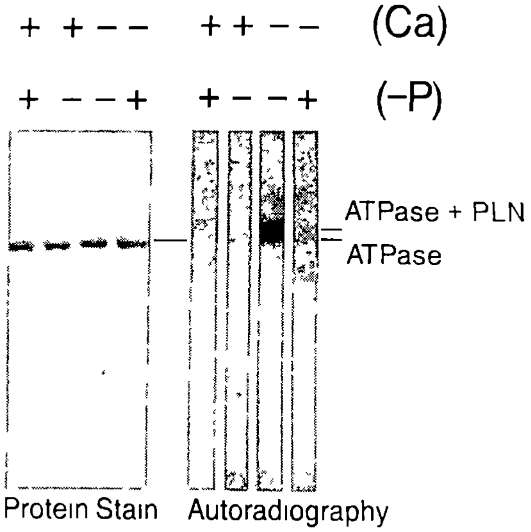

FIG 1 Crosslinking of Denny-Jaffe labelled PLN to the isolated SR ATPase *a*, Protein-stained SDS-polyacrylamide gel *b*, Autoradiograph of same gel Conjugated PLN crosslinked to the SR Ca^{2+}-ATPase (lane 3) The interaction between the two proteins was strongly inhibited by pre-phosphorylation of PLN (lanes 1 and 4) or by Ca^{2+} ions (lanes 1 and 2)

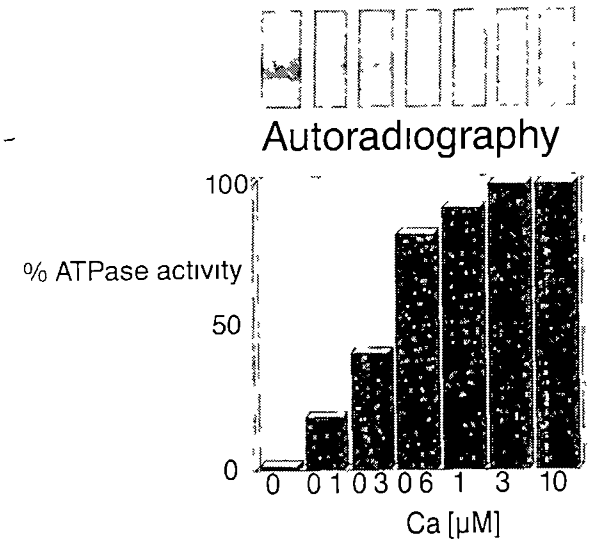
METHODS PLN was purified[1] and labelled with the Denny-Jaffe reagent in 0 1% $C_{12}E_8$ detergent (dodecyl octaoxyethylene glycol monoether), 10 mM phosphate buffer, pH 6 8, in the dark[17] Labelling was carried out in the presence of cyclohexadione to block all arginine residues As the N-terminus is blocked, the only group left to react with the reagent is the single lysine of PLN Using cold Denny-Jaffe reagent, about 5 mol azide per PLN pentamer could be incorporated SR ATPase was isolated from rabbit heart according to ref 18 The ATPase preparation (~1 mg ml^{-1}) was crosslinked[17] to the conjugated PLN (stoichiometric ratio 1 1, pump to pentamer) in a medium composed of 20 mM Tris-maleate, pH 7 0, 0 1% $C_{12}E_8$, 2 5 mM $MgCl_2$, and in the presence of either 0 5 mM EGTA (lanes 3 and 4) or 0 1 mM Ca^{2+} (lanes 1 and 2) If necessary, PLN was pre-phosphorylated (lanes 1 and 4) using the catalytic subunit of the cAMP-dependent protein kinase Results were identical when phosphorylation was carried out before or after conjugation of PLN to the Denny-Jaffe reagent Samples of protein (10 μg) were then run on 10% polyacrylamide/SDS-gels[19], stained with Coomassie brilliant blue (*a*), dried and autoradiographed (*b*) The molecular weight of the crosslinked ATPase population was altered by ~6,000 because boiling in sample buffer dissociates the PLN pentamer The sample buffer contained dithiothreitol, which on heating partially reduces the azo crosslink, thus explaining the width of the radioactive band The coupling efficiency was low (5-10%), which is usual in most photo-crosslinking reactions



◀ FIG 2 Calcium dependence of PLN binding to the SR ATPase *a*, Autoradiograph of SDS-polyacrylamide gel *b*, Calcium-dependence of ATPase activity Ca^{2+} ions in the submicromolar range strongly inhibit the interaction between PLN and the Ca^{2+}-ATPase (see the Ca^{2+}-dependent decrease in ^{125}I-labelled ATPase–PLN complex in *a*) There is a similar calcium dependence of ATPase activation under identical conditions (*b*) This indicates that the conformational change induced by calcium binding to the set of high-affinity binding sites on the ATPase is responsible for the inability of PLN to bind to the enzyme

METHODS The SR ATPase was crosslinked to non-phosphorylated, Denny-Jaffe-conjugated PLN as described in the legend to Fig 1 Medium was supplemented with 0 5 mM EGTA and different amounts of $CaCl_2$ to give the calculated free Ca^{2+} concentration Calcium dependence of ATPase activity was measured under the same conditions, but in the absence of modified PLN, using a coupled enzyme assay[20]

FIG 3 Isolation and amino-acid sequence analysis of the PLN-binding peptide from the SR ATPase *a*, Reverse-phase HPLC of peptides formed by cyanogen bromide digestion of ^{125}I-labelled SR ATPase *b*, Re-chromatography on an ion-exchange column of the fractions from *a* that contained the radioactivity Solid lines indicate absorbance at 206 nm and broken lines, radioactivity in c p m ▶

METHODS Isolated cardiac SR Ca^{2+}-ATPase (10 mg) was photolysed in the presence of 200 µg non-phosphorylated, Denny-Jaffe-conjugated PLN, as described in the legend to Fig 1 After reduction and carboxymethylation of thiol groups, PLN was cleaved off using 100 mM sodium dithionite[17] and removed from the solution by dialysis (cut-off range 50,000 M_r) This cleavage leaves the ^{125}I label attached to the ATPase domain that interacts with PLN The ATPase was then digested with CNBr and fractionated on a 300-Å, 7-µ, 250 × 10 mm C-18 RP column (0 1% trifluoroacetic acid in water to 100% *n*-propanol in 50 min) The broad radioactive peak was collected and diluted into 20% *n*-propanol, 10 mM Tris-HCl, pH 8 5 (buffer A), and then injected onto a Mono-Q column equilibrated in the same buffer A gradient of 0–0 5 M NaCl in buffer A was run over 60 min Radioactive fractions were desalted by reverse-phase HPLC and sequenced in an Applied Biosystems 470A sequencer with on-line detection Half of the phenylthiohydantoin amino acids released per cycle were injected onto the 120A HPLC unit of the system for analysis, and the other half counted to determine radioactivity in a Beckman gamma counter

FIG 4 The amino-acid sequence of the ^{125}I-labelled peptides obtained from rabbit cardiac muscle SR ATPase and from dog fast-twitch muscle ATPase is shown aligned with homologous regions in other ATPases (1) Rabbit slow-twitch muscle SR Ca^{2+}-ATPase[21], (2) rabbit fast-twitch muscle SR Ca^{2+}-ATPase[22], (3) human plasma membrane Ca^{2+}-ATPase[23], (4) sheep plasma membrane $Na^+ + K^+$ ATPase [24], (5) torpedo plasma membrane $Na^+ + K^+$ ATPase[25], (6) *Saccharomycas cerevisiae* H^+-ATPase[26], (7) *Neurospora crassa* H^+-ATPase[27], (8) *Escherica coli* K^+-ATPase[28], and (9) *Streptococcus faecalis* K^+-ATPase[29] Despite the high degree of homology found in all ATPases around the phosphorylation domain, the PLN-binding region is unique to the two isoforms of the SR Ca^{2+} pump and is not even found in the plasma membrane (PM) Ca^{2+}-ATPase

The domain of interaction of the ATPase with PLN has been identified Crosslinked ^{125}I-labelled PLN-ATPase complex was cleaved at the azo linkage of the Denny-Jaffe reagent using dithionite This removed PLN from its binding site while the ^{125}I label remained attached to the ATPase After removal of PLN by extensive dialysis, cyanogen bromide digestion of the ATPase gave two peptides, both carrying the ^{125}I label, which must therefore have contained the binding domain The peptides were purified (Fig 3) and sequenced Their molecular weights were identical, as judged from plasma desorption mass spectrometry, and their sequence was the same They differed only in the position of labelling of the two neighbouring lysines (arrows in Fig 4) Figure 4 shows that the peptide(s) originated from a region of the ATPase just C-terminal to the aspartyl residue that is phosphorylated during the transport cycle Binding of unphosphorylated PLN to this site could therefore be interfering with the formation of the high-energy phosphorylated intermediate E_1-P, with its transition to the E_2–P form, and/or with the hydrolysis of E_2–P, which is a rate-limiting step[16]

The Ca^{2+}-ATPase of the SR shares a high degree of homology with all other ATPases of the phosphorylation type In particular, the phosphorylation site is virtually identical in all these pumps (Fig 4) Strikingly, however, the site of PLN interaction is a unique feature of the SR ATPase(s) Thus, regulation by PLN of ATPase activity, other than in the SR type, would not be possible The PLN-binding domain is also found in the fast-twitch muscle isoform of the SR Ca^{2+}-ATPase (Fig 4), so it has been possible also to crosslink PLN to ATPase preparations isolated from dog and rabbit fast skeletal muscle SR The same lysine residues were labelled as in the slow-twitch/cardiac enzyme Independent experiments using PLN affinity column chromatography showed that ATPase from rabbit fast skeletal muscle SR bound to the column only when the ATPase was in the E_2 form (data not shown) Evidently the regulation of the Ca^{2+}-pumping activity in fast- and slow-twitch muscle SR depends on the differential expression of the regulatory protein PLN, rather than on intrinsic structural differences in the ATPase isoforms present in the two muscle types □

Yeast replication factor-A functions in the unwinding of the SV40 origin of DNA replication

Steven J. Brill & Bruce Stillman

Cold Spring Harbor Laboratory, Cold Spring Harbor, New York, 11724, USA

CELL-free replication systems for simian virus 40 (SV40) DNA are taken to be a model for the replication of eukaryotic chromosomes, because only one viral protein is required to supplement the replication proteins provided by a human cell extract. To prove that these cellular proteins function in chromosomal DNA replication we have begun to identify homologous proteins in an organism that can be genetically manipulated Here we report the identification of yeast replication factor-A (yRF-A) from *Saccharomyces cerevisiae* and show that it is functionally and structurally related to a human protein that is required for the initiation and elongation of SV40 DNA replication Yeast RF-A, a multi-subunit phosphoprotein, is similar to the human protein in its chromatographic behaviour, subunit structure and DNA-binding activity The yeast protein will fully substitute for the human protein in an early stage of the initiation of SV40 DNA replication. Substitution of yRF-A in the complete SV40 replication system, however, results in reduced DNA replication, presumably due to a requirement for species-specific interactions between yeast RF-A and the DNA polymerase complex

Human cell extracts that are supplemented with purified SV40 large tumour antigen (T-Ag) support replication of plasmid DNAs containing SV40 origin of replication sequences[1-3] After biochemical fractionation, the crude extract has been replaced by five purified proteins and one partially purified fraction (refs 4–7, see ref 8 for a review) One of these proteins, replication factor-A (RF-A), a multi-subunit protein with single-strand DNA (ssDNA)-binding activity[9-11], is required for the initiation of DNA replication by participating in the formation of an 'unwound complex' on the SV40 DNA template[5 12-14] This complex is an early intermediate in the initiation reaction and accumulates in the absence of dNTP precursors It is detected by the accumulation of a topologically underwound plasmid DNA (form U) after phenol extraction and agarose gel electrophoresis Form U DNA can be obtained in the absence of DNA synthesis by incubation of plasmid DNA containing the SV40 origin of replication with three purified components T-Ag, topoisomerase I and RF-A After the removal of the proteins, the unwound DNA is subjected to electrophoresis in an agarose gel in which form U DNA migrates slightly slower than form I DNA This 'unwinding' assay was used to screen yeast extracts for components with an activity able to replace that of human RF-A This assay was expected to detect heterologous ssDNA-binding proteins because the *Escherichia coli* ssDNA-binding protein (SSB), which functions during the initiation and elongation of *E coli* DNA replication, substitutes for human RF-A in this assay[15,16]

Crude yeast cell extracts were unable to substitute for RF-A in the unwinding assay An unwinding activity, however, could be detected in one fraction after chromatography of the extract on a ssDNA cellulose column The active fraction bound tightly to ssDNA cellulose, requiring 1 5 M NaCl and 50% ethylene glycol for elution, similar to the conditions that elute human RF-A The activity was further purified and found to co-fractionate on a Mono Q column with three polypeptides of relative molecular mass (M_r) 69,000 (69K), 36K and 13K (p69, p36 and p13, Fig 1*a* and *b*) The M_r of these polypeptides closely

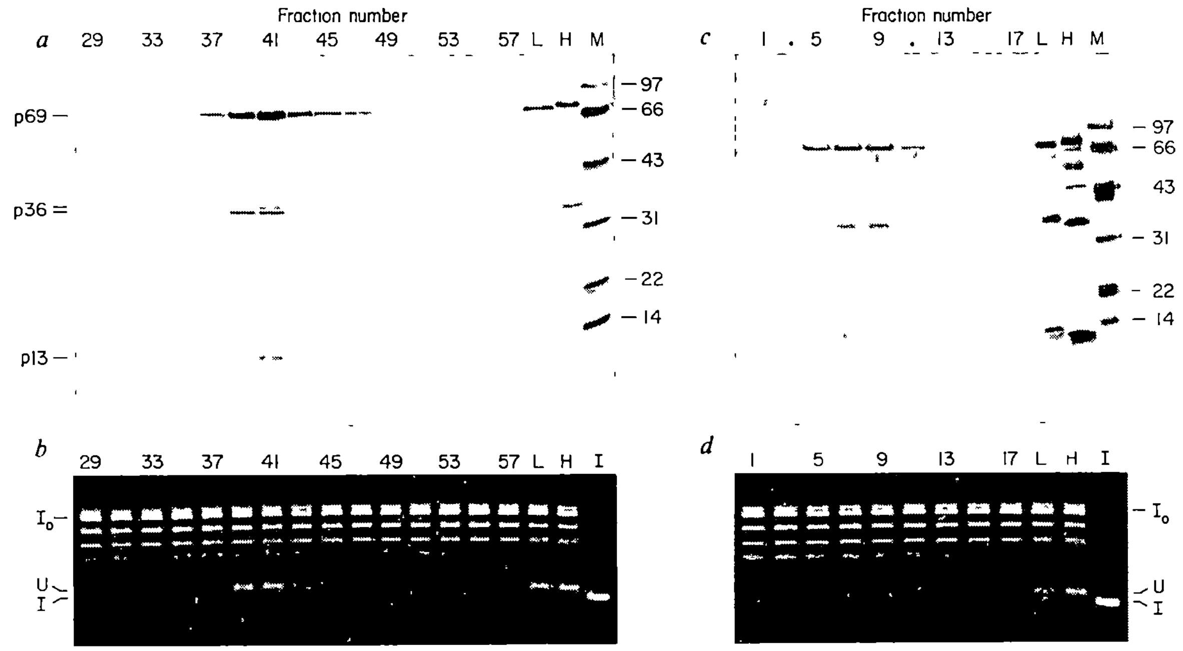

FIG 1 Co-fractionation of unwinding activity and yRF-A. *a*, SDS-PAGE (17%) and Coomassie-brilliant-blue-stain analysis of yRF-A fractions from a Mono Q column. The fractions shown represent the portion of the elution gradient from 115 to 360 mM NaCl. *b*, Unwinding assays across Mono Q. *c*, SDS-PAGE (17%) and silver-stain analysis of fractions from a glycerol gradient sedimentation of yRF-A. The fractions shown represent the entire gradient (18 fractions total). *d*, Unwinding assays across the glycerol gradient. Lanes L, load of each fractionation step, H, sample of human RF-A[10], M, relative molecular mass markers ($M_r \times 10^{-3}$). I_0, form I relaxed DNA, U, form U unwound DNA, I, form I DNA.

METHODS. Strain BJ926 (10 litres) were grown and lysed as previously described[18] except that the cells (160 g) were resuspended in 340 ml buffer A (25 mM Tris, pH 7.5, 1 mM EDTA, 10% glycerol, 1 mM DTT, 0.1 mM phenylmethylsulphonyl fluoride) with protease inhibitors (10 mM benzamidine, 100 μg ml^{-1} bacitracin, 1 μg ml^{-1} pepstatin A, 10 mM sodium bisulphite) and 1 M NaCl. The lysate was adjusted to 1 M NaCl, kept at 0 °C for 30 min, and centrifuged in a GSA rotor at 10,000 r.p.m. (16,200g at r_{max}) for 45 min. The supernatant (8.8 g protein) was adjusted to 0.5 M NaCl with buffer A and applied to a 2.5×8-cm Affi-gel Blue column. The column was washed with two volumes each of buffer A containing 0.5 M NaCl, 0.8 M NaCl and 2.5 M NaCl with 40% ethylene glycol. Peak protein fractions from the 2.5 M NaCl-ethylene glycol wash were pooled (350 mg protein), diluted to 0.5 M NaCl with buffer A and applied to a 2.5×6-cm ssDNA cellulose (USBC) column. This column was washed with two volumes each of buffer A containing 0.5 M NaCl, 0.75 M NaCl, and 1.5 M NaCl with 50% ethylene glycol. Peak protein fractions from the 1.5 M NaCl-ethylene glycol wash were pooled and dialysed against buffer A containing 200 mM NaCl and 20% sucrose. After clarification, this material (2.3 mg protein) was diluted to 100 mM NaCl with buffer A and applied to a Mono Q column (HR5/5). The column was washed with 4 ml buffer A containing 100 mM NaCl and eluted with a 10 ml linear gradient from 0.1 to 0.4 M NaCl. Fractions from this gradient (180–280 mM NaCl, peak, 220 mM NaCl) were pooled and dialysed against buffer A containing 25 mM NaCl and 20% sucrose. This procedure yielded 300 μg yRF-A at greater than 95% purity. Unwinding assays were performed as previously described[5]. Yeast RF-A (40 μg), Mono Q pool was adjusted to 0.1 M NaCl and separated on a 5-ml, 15–35% glyerol gradient in buffer A with 0.1 M NaCl (SW50.1 rotor, 49,000 r.p.m. (300,000g at r_{max}), 21 h)[4].

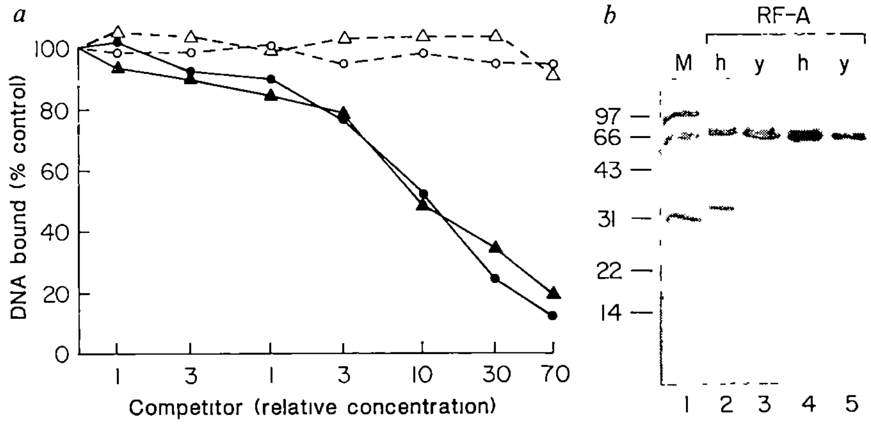

FIG 2 Single-strand DNA-binding activity of yRF-A. *a*, Competition of yRF-A binding to labelled ssDNA with double and single strand DNA. Human RF-A (triangles) or yRF-A (circles) was incubated with denatured ^{32}P-labelled pUC118 DNA in the presence of increasing amounts of double-strand pUC118 DNA (- - -) or single-stranded pUC118 DNA (——). *b*, Protein blot probed with ^{32}P-labelled DNA. Lanes 1, marker proteins, 2, 5 μg human RF-A, 3, 5 μg yRF-A, 4, 0.5 μg human RF-A, and 5, 0.5 μg yRF-A. In lanes 1–3, the nitrocellulose blot was stained with amido black to detect transferred proteins. In lanes 4 and 5, the nitrocellulose blot was probed with ^{32}P-labelled single strand pBR322 DNA. M, M_r markers ($M_r \times 10^{-3}$), h, human, y, yeast.

METHODS. *a*, Either hRF-A[10] or yRF-A (Mono Q pool) (50 ng) were incubated for 30 min at 0 °C with various amounts of unlabelled competitor DNA and 15,000 c.p.m. (5 ng) pUC118 DNA that had been digested with *Hin*dIII, filled-in with [α-^{32}P]TTP and Klenow fragment enzyme and thermally denatured. Competitor DNA consisted of pUC118 DNA digested with *Sma*I either before (double strand) or after (single strand) thermal denaturation. After the incubation the samples were filtered through alkalai-washed nitrocellulose[19] and counted. *b*, Proteins were separated by SDS-PAGE (17%), transferred to nitrocellulose, and either stained with amido black or probed[6] with thermally denatured pBR322 DNA that had been digested with *Hpa*II and filled-in with [α-^{32}P]dCTP and [α-^{32}P]dGTP.

in the complete replication reaction, although analysis of the small amount of replication products by agarose gel electrophoresis revealed topoisomers consistent with completely replicated molecules, similar to those obtained with human RF-A (Fig 4*b*)

Although yRF-A seems to fully substitute in the unwinding reaction, the ability of yRF-A to fully substitute in the complete replication reaction could depend on an additional function of RF-A We have recently shown that hRF-A stimulates both DNA polymerases α and δ, implicating a role for human RF-A in the elongation stage of DNA replication[20] Preliminary results indicate that yRF-A does not stimulate human DNA polymerase α It is probable that yRF-A, therefore, cannot efficiently substitute in the priming and elongation stages of SV40 DNA replication, because of a requirement for a species-specific interaction between RF-A and the priming-polymerase complex

The divergence of yeast and human RF-A is confirmed by the failure of both polyclonal and monoclonal antibodies, raised against human RF-A, to recognize yRF-A More recently, polyclonal antibodies have been raised against the individual subunits of yRF-A and they fail to bind to human RF-A (unpublished observation) This situation is similar to that involving the proliferating cell nuclear antigen (PCNA), another human cell replication factor that is required for SV40 DNA replication *in vitro*[8], and its yeast analogue yPCNA PCNA, from human and yeast sources, functions as an accessory protein for DNA polymerase δ and yeast DNA polymerase III, respectively Yeast PCNA fails to cross-react with antibodies raised against the mammalian protein and although yPCNA stimulates DNA polymerase δ, it does so poorly, the level of yPCNA required is 10-fold higher than the level of human PCNA required for stimulation[17]

The combined use of a mammalian cell-free system with biochemical and genetic analysis of yeast should provide an insight into eukaryotic chromosomal DNA replication A similar approach has recently been used for understanding other complex macromolecular processes, such as transcription and protein transport in eukaryotic cells The isolation of a ssDNA-binding protein from yeast that probably functions at the initiation stage of DNA replication will be a valuable entry point for understanding the mechanism of initiation of chromosomal DNA replication Because this event is highly regulated during the eukaryotic cell cycle, the components involved in the initiation of DNA replication provide attractive targets for growth regulatory processes The identification of yRF-A as a phosphoprotein should enable a biochemical and genetic analysis of those controls ☐

Induction of the *Escherichia coli* lactose operon selectively increases repair of its transcribed DNA strand

Isabel Mellon* & Philip C. Hanawalt

Department of Biological Sciences, Stanford University, Stanford,
California 94305-5020, USA

NUCLEOTIDE excision repair helps to ameliorate the lethal and mutagenic consequences of DNA damage by removing helix-distorting lesions from cellular genomes[1] We have previously analysed the removal of ultraviolet-induced cyclobutane pyrimidine dimers from specific DNA sequences in mammalian cells and demonstrated that transcriptionally active genes are preferentially repaired[2–4]. Additionally, we found that in rodent and human cells only the transcribed strand of the dihydrofolate reductase gene is selectively repaired[5]. Transcription is blocked by pyrimidine dimers in template DNA[6] and the selective removal of these lesions seems to be important for cell survival after irradiation with ultraviolet light[2,7,8] To determine whether this feature of repair is common to prokaryotes and eukaryotes and better to understand its mechanism, we have investigated repair in the two separate DNA strands of the lactose operon of ultraviolet-irradiated *Escherichia coli* We find a dramatic difference in the repair of the two strands only when transcription is induced. Most dimers are removed from the transcribed strand of the induced operon within five minutes of irradiation In the non-transcribed strand, repair is significantly slower and resembles that found in both strands of the uninduced operon Thus there seems to be a mechanism that couples nucleotide excision repair and transcription

The lactose operon of *E coli* is well characterized and its transcription can be modulated[9] It contains three genes in a single transcription unit, *lacZ*, *lacY* and *lacA*, which encode β-galactosidase, galactoside permease and thiogalactoside transacetylase, respectively Synthesis of the polycistronic message is induced by β-galactosides such as lactose or isopropyl-β-D-thiogalactoside (IPTG) In the absence of inducer, initiation of transcription is very infrequent

Using our earlier methodology[5 10], we measured the removal of pyrimidine dimers from the respective DNA strands of specific restriction fragments of the *lac* operon in *E coli* K12 cells grown in the presence or absence of IPTG After irradiation with ultraviolet light, culture samples were collected immediately to determine the initial frequency of dimers, and then further samples were taken after incubating for increasing periods of time to allow repair High molecular weight DNA was purified and treated with restriction enzymes Only unreplicated DNA was examined to avoid complication by dimer-free DNA generated by replication, which would cause an overestimate of the amount of repair Two aliquots of each DNA sample were analysed, one of which was treated with T4 endonuclease V to produce a single-strand break specifically at each cyclobutane pyrimidine dimer[11] Samples were electrophoresed in parallel under denaturing conditions and the DNA transferred to a support membrane These Southern blots were then hybridized with ^{32}P-labelled strand-specific RNA probes to quantitate the full-length restriction fragments at each time point As repair occurs, fewer T4 endonuclease-sensitive sites remain in the DNA, resulting in fewer strand breaks by endonuclease and more full-length restriction fragments in the enzyme-treated sample The average number of dimers per fragment was calculated from the ratio of full-length restriction fragments in the enzyme-treated and untreated samples, using the Poisson expression

---

* Present address Department of Pathology CC452 Markey Cancer Center University of Kentucky Lexington Kentucky 40536-0093 USA

Two restriction fragments were examined the 6 6 kilobase (kb) *Apa*I-*Sst*II fragment that contains 1 5 kb of sequence outside the coding region of the operon, and the 5 2 kb *Nar*I-*Nru*I restriction fragment that resides almost entirely within the transcription unit (Fig 1*a*) Strand-specific RNA probes (Fig 1*b*) were obtained by subcloning a fragment of the *lacZ* gene into the multiple cloning site of the vector pGEM-3Z The construct, pZH10, contains the *lacZ* sequence flanked by two different phage RNA polymerase promoters oriented in opposite directions Linearizing the plasmid with *Eco*RI and incubating with SP6 RNA polymerase generates an RNA probe specific for the transcribed strand of the operon, whereas linearizing with *Bam*HI and incubating with T7 RNA polymerase generates an RNA probe specific for the non-transcribed strand

Repair was examined in the 6 6 kb *Apa*I-*Sst*II fragment of the uninduced or induced operon at 2 5, 5, 10 and 20 min after irradiation with ultraviolet light ($40\ \mathrm{J\,m^{-2}}$) (Fig 2) Levels of β-galactosidase were 4,800 units and 11 units[12] in cultures grown in the presence or absence of IPTG Southern blots were hybridized with the probe specific for the transcribed strand, that probe was removed and the blot was then hybridized with the probe specific for the non-transcribed strand The initial level of damage was the same in each strand, whether or not transcription had been induced Visual comparison of the enzyme-treated samples probed for the two different strands at each repair time point reveals similar amounts of full-length restriction fragments when the operon was not induced, but significantly more full-length fragments for the transcribed strand when the operon was induced Quantitation indicates that there is a dramatic difference in the rate of repair in the transcribed and non-transcribed strands of the operon only when transcription was induced with IPTG (Fig 3) Within 5 min, most dimers were removed from the transcribed strand of the induced operon, whereas little repair was detected at this time in the non-transcribed stand or in either strand of the uninduced operon The repair rates in each strand of the uninduced operon and in the non-transcribed strand of the induced operon were comparable Repair was almost complete within 40 min after irradiation (data not shown)

This study provides two important observations (1) Selective removal of pyrimidine dimers from the transcribed strand of an active gene is not unique to mammalian or even eukaryotic excision repair Repair in the induced *lac* operon of ultraviolet-irradiated *E coli* resembles repair in the active dihydrofolate reductase (*DHFR*) gene of ultraviolet-irradiated human cells[5] repair in the transcribed strand is significantly faster than that in the non-transcribed strand, but most dimers are removed from both strands within one generation period in the respective cell types (2) This selective removal of pyrimidine dimers from the transcribed strand of a gene is abolished in the absence of significant levels of transcription

Bockrath and Palmer[13] studying ultraviolet-irradiated *E coli* noted a more rapid decline in mutations generated by lesions that were deduced to be in the transcribed strand of a glutamine transfer RNA gene than in mutations generated by lesions in the non-transcribed strand of the gene This difference in mutation frequency did not occur in a mutant deficient in nucleotide excision repair They suggested that selective repair of the transcribed strands of the $^{\mathrm{Gln}}$tRNA genes might account for the observed decline in mutation frequency, a notion strengthened by the demonstration that the strand-specific loss of mutations is unrelated to the polarity of replication[14] We have been unable to analyse repair in the respective strands of the $^{\mathrm{Gln}}$tRNA genes (unpublished data) because the method described here requires very high doses of ultraviolet light to examine small sequences A similar strand bias in mutation frequency was noted by Bockrath *et al*[15] using ethyl methanesulphonate, and Reed and Hutchinson[16] have reported a large bias in mutation frequency towards the non-transcribed strand of the λ *cI* gene in *E coli* treated with another alkylating agent, *N*-methyl-*N*′-nitro-*N*-nitrosoguanidine It will be important to determine whether differences in the removal of DNA damage from the respective strands of active genes in *E coli* and mammalian cells correlate

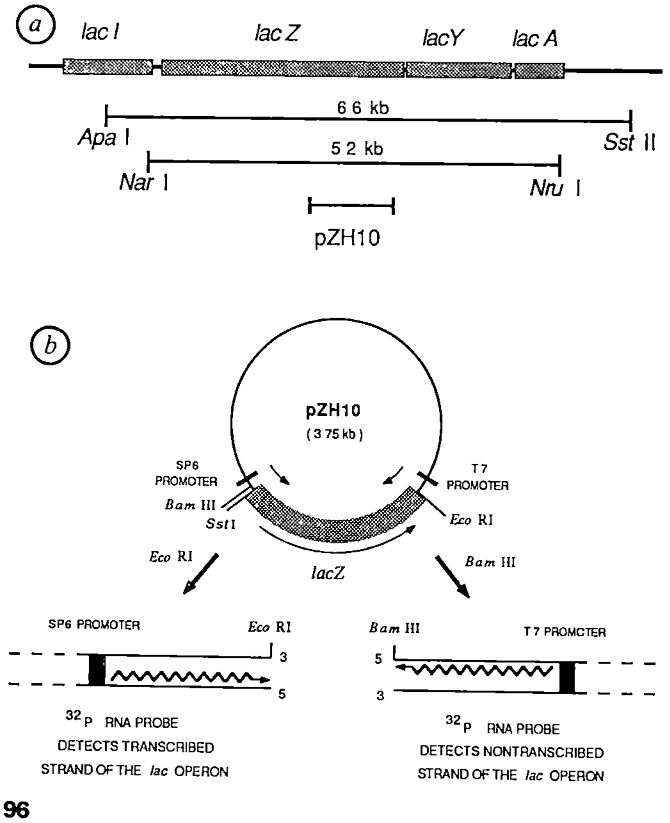

FIG 1 *a*, Map of *E coli* lactose operon The positions of the genes within the operon, *lacI*, the *lacZ* insert in pZH10 used to generate probes, and relevant restriction enzyme sites are shown *b*, Illustration of the plasmid pZH10 and application to generate strand-specific RNA probes Plasmid pZH10 contains 1 kb of the *E coli lacZ* gene (thick arc) and the vector sequences from pGEM-3Z (thin line), which include the SP6 and T7 RNA polymerase promoters (heavy bars) The directions of transcription of the *lacZ* gene *in vivo* and the SP6 and T7 promoters are indicated by arrows around the plasmid diagram Strand-specific RNA probes are indicated by wavy lines

METHODS Restriction enzyme sites in the *lac* operon region were obtained from sequence data (accession numbers J01636, J01637, K01483, K01793) in the GenBank Data Bank[27] (release 59) using the Bionet resources (Intelligenetics) The plasmid pZH10 was constructed by isolating a 1 kb *Eco*RI-*Sst*I *lacZ* fragment from the plasmid pZH1 (ref 28) and subcloning it into the *Eco*RI-*Sst*I sites of pGEM-3Z Cultures of DH5alpha (BRL) were transformed with the ligation products, and recombinants were selected as white colonies on LB plates supplemented with $100\ \mu\mathrm{g\,ml^{-1}}$ ampicillin, 0 5 mM IPTG, and $40\ \mu\mathrm{g\,ml^{-1}}$ X-Gal Plasmids were isolated and purified by two consecutive bandings in CsCl/ethidium bromide gradients Plasmid DNA was digested with *Bam*HI (*Sst*I generates 3′ protruding ends) or *Eco*RI and RNA probes were prepared as previously described[5]

FIG. 2 Autoradiograph illustrating repair in the *lac* operon when it is uninduced and induced. DNA was isolated at the times indicated above the lanes, restricted with *Apa*I and *Sst*II, and not treated (−) or treated (+) with T4 endonuclease V. Samples (0.5 μg) of DNA were loaded. ^{32}P-labelled RNA probes were made from pZH10.

METHODS. Cells were grown, irradiated with ultraviolet light, and incubated as previously described[29], with some modifications. Cultures of *E. coli* K-12 strain SR108 ($F^{-}\lambda^{s}$*thyA deo*$^{-}$) (provided by A. Ganesan) were grown at 37 °C in Difco Bacto Minimal Broth Davis, supplemented with 0.4% glucose, 0.05% casein hydrolysate, $2\ \mu g\ ml^{-1}$ thymine and $0.5\ \mu Ci\ ml^{-1}$ [^{3}H]thymine. Cultures were grown to a density of $\sim 3 \times 10^{7}$ cells per ml, collected on 0.22-μm pore size Millipore filters (GSWP) by filtration, and resuspended at the original density in unsupplemented Minimal Broth. Cultures were irradiated with 40 J per m^{2} of ultraviolet light (254 nm) and incubated for the specified repair periods in Minimal Broth containing 0.4% glucose, 0.05% casein hydrolysate and $10\ \mu g\ ml^{-1}$ 5-bromouracil. For studies of repair in the induced *lac* operon, IPTG (0.1 mM) was included in the medium before and after ultraviolet radiation. (Because glucose was present in the medium, the operon was not fully induced.) β-Galactosidase levels were assayed as previously described[12], except cells were permeabilized by freeze-thawing instead of by toluene treatment. High molecular weight DNA was isolated[29], treated with restriction enzymes, sedimented to equilibrium in CsCl density gradients to remove replicated DNA and treated with T4 endonuclease V (ref. 5). Samples of DNA (0.5 μg) were treated with 1 μl T4 endonuclease V (incision activity of enzyme preparation, 5.5×10^{11} sites per $\mu l\ min^{-1}$ at 37 °C). Samples were electrophoresed in 0.6% alkaline agarose gels and the DNA was transferred to a Genatran nylon membrane. The membrane was hybridized with ^{32}P-labelled probe, washed and exposed to X-ray film as described[5]. The amount of radioactivity hybridized to the fragment of interest was determined by scanning densitometry of the autoradiograph.

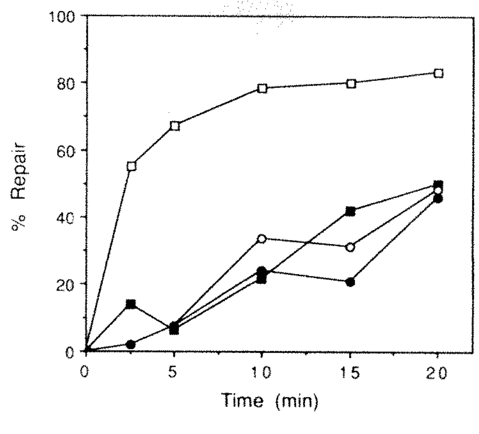
with mutation frequencies in these strands, but this examination may be complicated by other cellular processes that influence mutation frequency[17-19].

There is strong evidence that transcription is blocked by pyrimidine dimers in template DNA in both prokaryotic and eukaryotic cells[6]. Initiation occurs normally on the damaged template (assuming no damage in the initiation region) and chain elongation proceeds until a dimer is encountered, resulting in premature termination. It is likely that only damage to the template strand produces this effect; this has been directly shown *in vitro* for psoralen monoadducts[20]. A repair mechanism that specifically detects transcription-blocking DNA damage should be advantageous to the cell if maintenance of constant levels of essential transcripts is critical for cell survival. As ultraviolet irradiation actually induces the transcription of a collection of genes[21] while producing DNA lesions that block transcription elongation, the rapid removal of transcription-blocking lesions should facilitate the expression of such ultraviolet-induced genes. It is tempting to speculate that for some genes, the purpose of ultraviolet-induced transcription is not simply to provide a gene product, but rather to ensure that DNA damage is rapidly removed from certain essential sequences.

The molecular details of nucleotide excision repair are more complicated and less well understood in mammalian cells than in *E. coli*. A larger number of genes are involved and although some have recently been cloned[22,23], their functions are unknown. It is also not clear how heterogeneities in the chromatin structure or organization of particular sequences in the complex mammalian genome affect DNA repair. Indeed, we originally suggested that differences in the repair of transcriptionally active and inactive sequences in mammalian cells are due to differences in their chromatin structure[2,4]. Our finding that preferential repair of the *DHFR* gene in human and rodent cells is due to selective repair of only the transcribed strand of the gene challenged this model. The strand-specific repair in the *E. coli lac* operon indicates that features of eukaryotic chromatin structure are not required for selective removal of damage from active genes. Furthermore, as this feature of repair has been conserved in bacteria and mammalian cells, it is not something that just evolved in higher eukaryotes as a mechanism to deal

FIG. 3 The effect of transcription on pyrimidine dimer removal from the DNA strands of the *lac* operon. The average number of dimers was measured in the 6.6-kb *Apa*I-*Sst*II restriction fragment at 0, 2.5, 5, 10 and 20 min after irradiation (40 J m^{-2}) and in the 5.2-kb *Nar*I-*Nru*I restriction fragment at 0, 5, 10, 15 and 20 min after irradiation (40 J m^{-2}). Values at 5, 10 and 20 min are an average of results from the two fragments. T (open symbols), transcribed strand; NT (filled symbols), non-transcribed strand; squares, induced; circles, uninduced.

METHODS. The average number of dimers per fragment was calculated from the percentage of fragments that had no dimers ('zero class') by using the Poisson expression (number of dimers per fragment = $-\log_e$ of the zero class). The zero class is equal to the ratio of the amount of full-length fragments in the enzyme-treated and untreated samples.



with the organization of sequences within their complex genomes.

A comprehensive description of nucleotide excision repair has only been achieved for *E. coli*[24,25]. Most, if not all, of the genes involved have been cloned and their products studied *in vitro*. At least six proteins are involved: UvrA, UvrB and UvrC, assembled in an 'excinuclease complex', and UvrD, DNA polymerase I and DNA ligase. It is thought that the distortion of the DNA helix produced by the pyrimidine dimer (or bulky DNA adducts), rather than the damage itself, is the substrate for the UvrABC complex. Two incisions are made in the DNA strand near the damage: the eighth phosphodiester bond 5′ to, and the fourth or fifth phosphodiester 3′ to a pyrimidine dimer are cleaved. The oligonucleotide containing the dimer is removed, a repair patch is synthesized using the complementary strand as a template, and ultimately the repair patch is ligated to the contiguous parental DNA strand. The strand-specificity in the repair of the induced *lac* operon demonstrated here indicates an association or coupling between transcription and nucleotide excision repair. Considering the ultraviolet-sensitive mutants that have been characterized in *E. coli*, it seems unlikely that the preferential repair of the transcribed strands of active genes is carried out by an entirely different and as-yet-uncharacterized repair system. It is likely that selectivity is imposed by targeting of the UvrABC complex to damage in the transcribed strand. There need not be a specific factor whose sole role is to mediate such targeting. For example, an RNA polymerase complex blocked at a lesion in the transcribed strand may itself facilitate recognition. This could be analogous to the mechanism whereby *E. coli* photolyase, an enzyme that specifically binds and photo-reverses pyrimidine dimers, actually stimulates the removal of dimers by the UvrABC excision nuclease[26]. Studies using the genetic and biochemical tools available in *E. coli* are needed to test this model, which should enhance our understanding of transcription-associated DNA repair in both bacteria and mammalian cells. ☐

Engineering monoclonal antibodies

J.D. Rodwell

Efforts to alter the mAb component of pharmaceuticals have focused on making them more human-like and smaller. Ultimately, the smallest molecular recognition unit derived from antibodies may be a single complementarity region.

MURINE monoclonal antibodies (mAbs) conjugated to drugs, isotopes, or toxins are being utilized as the targeting components of diagnostic and therapeutic agents for cancer, cardiovascular and other diseases. However, because of the limitations of administering nonhuman proteins, efforts to engineer new generations of antibodies, or antibody-like molecules, are already underway in both the biotechnology industry and in academe. These efforts are directed towards making the antibodies more human-like, smaller in size, or both (Fig. 1), with the aim of lowering the immunogenicity of these proteins in man and optimizing their target penetration and pharmacokinetic characteristics.

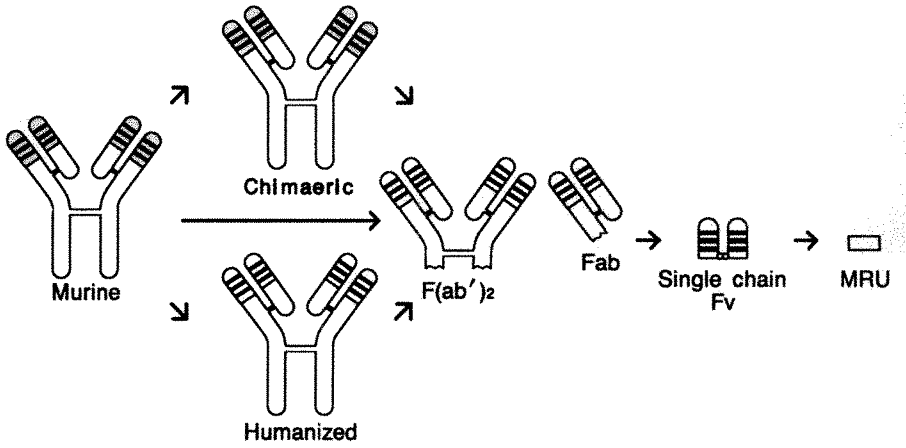

FIG. 1 Efforts to alter the mAb component of pharmaceuticals have led to the development of chimaeric, CDR-grafted (humanized) antibodies and to progressively smaller molecules.

mAb immunogenicity

One way to decrease mAb immunogenicity, as described by Morrison and her colleagues[1], involves the development of 'chimaeric' antibody technology. Rearranged DNA encoding mouse variable (VH, VL) regions is fused to DNA encoding human constant heavy and light chains. On expression, interspecies antibody chimaeras are obtained, with the same antigen-binding specificity as the parent molecule. Because most of the protein comprises human amino acid sequences, these antibodies should be less antigenic. A recent report by LoBuglio *et al.*[2] suggests that this approach may, indeed, result in reduced immunogenicity. A chimaeric antibody derived from the mouse monoclonal 17-1A was administered to patients with metastatic colon cancer. Compared to the parent murine antibody, the chimaeric molecule was substantially less immunogenic, with only one in 10 patients developing an antibody response.

Another approach is CDR (complementarity determining regions) grafting, which was developed by Winter and his colleagues[3]. This technique involves incorporation of the CDRs of mAbs into an expression system encoding human variable and constant regions. As the resulting 'humanized' antibodies contain only a small fraction of the amino acid sequence of mouse origin, it was reasoned that there would be little problem with immunogenicity. In a preliminary communication[4], Hale *et al.* reported remission in two non-Hodgkin lymphoma patients who received daily doses of 1–20 mg of a humanized mAb (CAMPATH-1-H) over 43 days. Significantly, neither patient developed a detectable immune response to the antibody.

Molecular size

While the above approaches may reduce patient sensitization to injected antibodies, they do not deal with the problem of molecular size. One potential solution is the use of antigen-binding fragments (Fabs), which penetrate target tissue better and clear from blood more rapidly than intact antibodies. As both chimaeric and humanized antibodies can be substrates for Fab production, Fabs produced in this way offer the same advantages over intact antibodies as mouse Fabs, while retaining lower immunogenicity. For diagnostic imaging of highly vascularized regions, such as thrombi, background clearance of labelled Fabs through the kidneys allows more rapid visualization of damaged myocardium. For tumour therapy, where the goal is to deliver a cytocidal dose of an appropriate isotope, drug, or toxin to as many target cells as possible, Fabs penetrate tumours more effectively, producing a more even distribution[6]. The cytotoxic efficacy of therapeutic isotopes may be expected to rise with better and more uniform tumour penetration.

The underlying assumption that smaller molecular size is better has also been addressed by the preparation of antigen-binding Fv fragments and 'single-chain' antibodies. Fvs are specific variable regions pairs (VH and VL), and have been expressed in *Escherichia coli*[6] and myeloma cells[7]. Single-chain antibodies are an interesting variation on this approach, in that VH and VL genes are joined together by a DNA segment encoding a peptide. This peptide is capable of bridging the carboxy terminus of one V domain and the amino terminus of the other, resulting in an Fv-like molecule synthesized as one continuous amino acid polymer. This approach has been reported to yield a properly folded (and paired) VH-VL gene product with the same antigen-binding characteristics as the antibody from which it was derived[8,9].

Future directions

All of these new approaches promise to improve upon results achieved with intact murine mAbs, and so we are developing strategies for the clinical evaluation of each approach. However, simplification of the molecular recognition component of this new generation of pharmaceuticals will not end here. At least two independent groups have reported that peptides, each representing the sequence of a single CDR from a mAb, can mimic the specificity of the parent molecule.

Williams *et al.*[10] have shown that a peptide with the sequence of the second CDR of the light chain of mAb 87.92.6, which binds to the reovirus type-3 receptor on cells, mimics the ability of the antibody to 'down-regulate' the receptor and inhibit DNA synthesis. Taub *et al.*[11] have described a peptide with the sequence of the third CDR of the heavy chain of PAC1 — an antibody specific for the GP IIb-IIIa complex on activated human platelets. Like the parent antibody, this peptide inhibits the binding of fibrinogen to platelets and also inhibits the binding of the PAC1 antibody itself. In both cases, the CDR peptides have homology with the sequence of the 'native' protein ligand.

Williams' peptide has sequence homology with the reovirus 3 haemagglutinin, and Taub's peptide has sequence homology with a region of fibrinogen that binds to the GP IIb-IIIa complex.

The CDRs of antibodies may, therefore, be an important source of amino-acid seqüence information that would facilitate the preparation of small recognition elements. The molecular weights of these recognition elements would be as low as a few per cent of the weight of an IgG antibody. Consequently, these elements, conjugated or fused to diagnostic and therapeutic effector molecules, would constitute an important new class of self-targeting pharmaceuticals.

The clinical potential for the diagnosis and treatment of human diseases with self-targeting pharmaceuticals using mouse mAbs is finally being realized. Knowledge derived from the use of intact antibody conjugates will allow further innovation as each component (molecular recognition, effector) is better understood. We can expect new generation(s) of antibody-like recognition units to be engineered using molecular surgery to remove structures that have evolved for functions secondary to antigen binding. □

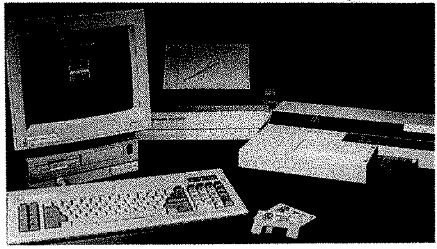
Reader Service No.50

Biology's soft cell

Highlights at next week's American Society for Cell Biology Annual Meeting in Houston, Texas include an interactive 3-D graphics software package and formulin-free tissue fixative.

FLOW Laboratories, exhibiting in booth 1241, has two new **PC-based microplate readers**, designed to scan a 96-well plate in less than two seconds (*Reader Service No. 101*). The £5,495 (UK) Multiskan Plus MKII and £6,950 (UK) Multiskan MCC/340 MKII PC systems come complete with microplate reader, IBM PC/XT or compatible, monochrome monitor, data capture and analysis software and 80-column printer. Switching assay routines is as simple as changing the disk, says Flow. The standard curve and sample results can be viewed via the monitor or printed as hard copy. The Entry Level Computing software provides statistical analyses, including mean minimum, maximum, delta, standard deviation, delta percentage and coefficient of variance for each row, column and whole plate. In addition to the five measurement modes, and nine calculation modes, the more advanced Multiskan MCC/340 MKII has a multiwavelength mode and an eight filter wheel for automatic dual wavelength reading.



Microplate reading IBM-compatibly.

In a fix

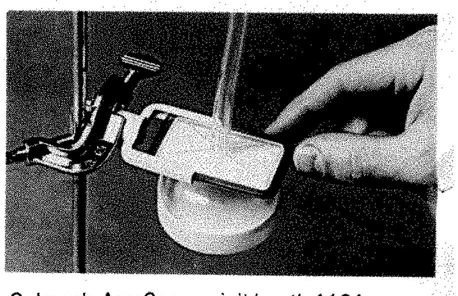
Zymed Laboratories are offering — OmniFix — **formulin-free tissue fixative** (*Reader Service No. 102*). This alcohol-based, odourless tissue fixative is, says the company, less toxic than formaldehyde and can be used with common staining techniques, such as peroxidase anti-peroxidase, avidin-biotin complex and streptavidin-peroxidase. According to Zymed, fixation times are reduced as OmniFix penetrates tissues more readily than formulin. Zymed recommends that tissues should be immersed for at least two hours. OmniFix is supplied ready-to-use in 1-, 5-, and 55-gallon polyethylene containers, and samples are available on request. Zymed will be in booth 1215.

According to Vector Laboratories, their Vectabond **tissue section adhesive** can significantly increase the adherence of both frozen and paraffin-embedded tissue sections to glass slides (*Reader Service No. 103*). Vectabond chemically modifies the glass, says Vector, to form an adherent surface that is suitable for all types of tissue sections and *in situ* hybridizations, while avoiding the instability and protease susceptibility problems associated with conventional adhesives. Vectabond costs $35 (US) for a 7-ml concentrate that makes 350 ml of treatment solution — enough for at least 500 slides, says Vector, who will be exhibiting in booth 749.

Culture conveniences

According to Becton Dickinson Labware, increased cell production is possible with their new line of Falcon brand **expanded surface roller bottles** (*Reader Service No. 104*). The longitudinal pleat design of the roller bottles improves cell yields and reduces the amount of trypsin required for cell harvesting, says the company. Other design features of these high-grade polystyrene roller bottles include a viewing side panel and a patented plug seal cap that reduces the risk of leakage and contamination, says Becton Dickinson. The Falcon brand roller bottles are sold in cases of 20 bottles for $144 (US). The company will be exhibiting in booths 1501/1503.

Using Gelman Sciences' AcroCap **presterilized disposable filters**, the company says serum-free culture media, media additives and buffers can be filtered at flow rates of 200 ml per minute (*Reader Service No. 105*). The AcroCap filters incorporate 15 cm^2 of Supor membrane, which is designed to filter up to 3 litres. The filling-bell attachment fits over wide-mouth cell culture bottles and, says Gelman, reduces the risk of contamination when filtering directly into sterile flasks. A 0.02 μm PTFE vent is incorporated into the filter's design to help prevent air blockage. The filters can attach to standard 0.25-inch tubing and can be used in conjunction with a peristaltic pump or repeating syringe. AcroCap filters come in 0.2 μm and 0.45 μm pore sizes and



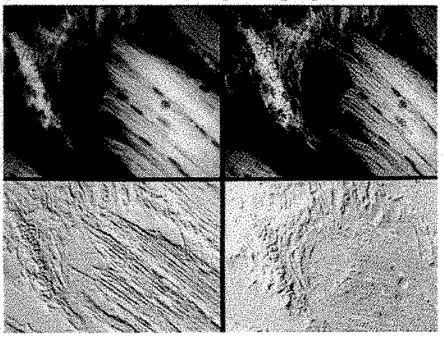
Gelman's AcroCap — visit booth 1101.

cost $35 (US) for 10 filters. Gelman Sciences will be in booth 1101.

The right image

Visitors to booth 1042, can see VoxelView — an **interactive volume rendering software system** — from Vital Images, Inc., which allows the user to visualize and manipulate 3-dimensional data sets in real time (*Reader Service No. 106*). VoxelView graphically reconstructs objects from 3-D voxel building blocks without, says Vital Images, any loss of complexity or resolution, and at speeds of up to 4 million voxels per second. The system can render data from sources as diverse as confocal microscopes, medical imaging systems, histological sections and molecular models. Using interactive pop-up menus, a pictorial data catalogue and graphical control of rendering parameters, the user can adjust image contrast/magnification, assign pseudocolour to images, minimize artefacts, adjust lighting and transparency, rotate and view data from any angle. Objects or phenomena deemed to be short-lived can, says Vital Images, be saved as 3-D computer images. VoxelView is designed to run on any Silicon Graphics 4D/GT or GTX series workstation, and is delivered as a 0.25-inch tape cartridge complete with user's guide.

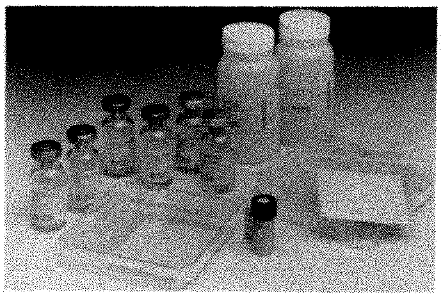
Universal Imaging Corporation, exhibiting in booths 128, 130 and 132, will be demonstrating the Image-1/AT combined **image processing and analysis system** (*Reader Service No. 107*). The $16,900 (US) Image-1/AT Combined System runs on IBM AT-compatible computers and has menu-driven software. The video-processing board allows video-rate image processing and high-speed graphics. Other functions include real-time image averaging with background subtraction, object counting and sizing, image sharpening, zoom and roam, 3-D image generation from optical sections, gel scanning and densitometry, text and graphics overlays. Images can be stored on magnetic disk or on an optional optical memory disk recorder. Universal emphasizes the system's built-in flexibility in that users can produce custom menus and journals — user-defined sequences of commands for repeat operations —which eliminate the need for laborious programming and which can be recalled by a single keystroke command.



Video viewing, courtesy Universal Images.

Assays, etc.

Advanced Magnetics, Inc are offering two new **immunoblot assay kits** for the measurement of phosphatidylinositol-4-monophosphate (PIP) and phosphatidylinositol 4,5-bisphosphate (PIP_2) (*Reader Service No. 108*). Samples and standards are bound to a nitrocellulose membrane and incubated overnight with monoclonal PIP antibody. The membrane is washed and incubated with goat anti-mouse IgM-HRP. The HRP substrate is developed with diaminobenzidine. Sample concentrations are determined by performing a colour comparison of sample and standard dots on the membrane. Each $395 (US) PIP and PIP_2 kit comes with sufficient reagents for 100 tests. AMI will be in booth 319.



Phosphatidylinositol phosphate kits.

Promega Corporation, exhibiting in booths 414/416, has **CAT reporter systems** for the direct assay of gene regulatory elements by measuring chloramphenicol acetyltransferase (CAT) activity (*Reader Service No. 109*). Genomic DNA fragments containing putative regulatory sequences are cloned into specially-constructed plasmids containing the CAT reporter gene. Four $55 (US) pCAT plasmids are available — pCAT Basic, pCAT Enhancer, pCAT Promoter and pCAT Control — all of which share a common pUC19 backbone and express CAT activity in eukaryotic cells. Promega's CAT reporter system offers two methods for monitoring CAT enzyme activity in transfected cells: liquid scintillation counting or thin-layer chromatography. The LSC assay takes 2-3 hours and can detect 3×10^4 units (2 pg) of CAT, says Promega. The TLC assay takes longer, is less sensitive, but provides visual confirmation of assay results by autoradiography. The CAT enzyme assay, which includes 100 units chloramphenicol acetyltransferase, 25 ml Tris-HCl and 255μl *n*-butyryl-CoA, costs $75 (US). ☐

These notes are compiled by Diane Gershon from information provided by the manufacturer. To obtain additional information about these products, use the reader service card bound inside the journal. Prices quoted are sometimes nominal, and apply only within the country indicated.

LINCOLN COLLEGE

(University from 1990)

New Zealand

PROFESSOR OF SOIL SCIENCE

The Council of Lincoln College invites applications from suitably qualified men and women for the Chair of Soil Science. The Chair is one of 16 at the College and the Council is anxious to fill the position with an appointee of high standing because of its significance, not only to the College, but also to New Zealand.

Applicants should hold an advanced degree in an appropriate discipline of Science and have an established record of research and teaching in Soil Science. Applicants should have a proven interest in the wider role of soils in the environment, with a competence in any of the major branches of Soil Science. The appointee will be expected to foster and develop the teaching, research and extension activities of the Department as a whole and to contribute to the research programme in his/her own field.

It is anticipated that the successful applicant will be appointed as Head of Department for an initial period of three years and will be responsible to the Principal for the administration of the Department.

Lincoln College will be granted autonomous University status in 1990. The 50 ha campus is 21 km south of the City of Christchurch. There are approximately 2000 students on Campus. Christchurch is the third largest city in New Zealand, the largest in the South Island, with a population of approximately 300,000 people and is served by direct international flights from Australia, Asia, United States of America and the United Kingdom.

Salary will be paid at a step in the range of NZ$77,000 – NZ$96,000 per annum. Salaries are reviewed annually. Expenses incurred in taking up the appointment will be reimbursed up to specified limits. Government Superannuation is available.

Further information about the position including details of the structure and academic functions of the Department, application procedure, travel and removal expenses, housing assistance and conditions of appointment are available from **Appointments (37081) Association of Commonwealth Universities, 36 Gordon Square, London WC1H 0PF, UK, or from A.J. Sargison, Registrar, PO Box 94, Lincoln College, Canterbury, New Zealand, Fax No. (64)(3) 252-965,** with whom applications quoting vacancy no 89/51 close on **15 January 1990.**

Lincoln College is an equal opportunity employer (W6665)A

UNIVERSITY OF ABERDEEN

DEPARTMENT OF ANATOMY

LECTURER

Applications are invited for the above post, tenable for five years. The appointee will be expected to attract external funding for and to conduct active quality research in the preferred areas of Cell Biology, Neurobiology or Developmental Biology, to assist in teaching gross anatomy to medical students and to participate in and develop modular degree courses for science students. The Department has research facilities for light and electron microscopy, stereology, computer-assisted image analysis and cell/tissue culture.

Initial salary will be on the Lecturer scale £10,458-£20,469 per annum with appropriate placing.

Further particulars and application forms from the **Personnel Office, The University, Regent Walk, Aberdeen AB9 1FX (tel 0224 273500),** to whom applications (2 copies) should be returned by 24 November 1989 quoting reference number JA/070. (1977)A

Mervin Bovaird Center in Molecular Biology and Biotechnology

■ ■ ■

MICROBIOLOGIST

MOLECULAR BIOLOGIST/VIROLOGIST

MOLECULAR IMMUNOLOGIST

TRANSGENIC MOUSE EXPERT

Due to major funding acquisitions through **The Mervin Bovaird Foundation** and a cooperative **Center of Excellence in Molecular Medicine**. The University of Tulsa is expanding its tenure-track faculty.

Researchers will be provided renovated laboratory space, funded post-doctoral positions, and generous start-up monies. **The transgenic mouse facility is guaranteed five years of substantial funding including technician in addition to start-up monies**. Requirements: Ph.D., postdoctoral experience, publication record indicative of the potential to maintain an externally funded research program. Salary and rank commensurate with experience. Faculty are expected to teach undergraduate and graduate students, and to maintain a record of productivity in scholarly research.

The department has sixteen faculty and offers BS, MS, and Ph.D. degrees. Extramural funding in 1987-89 totaled more than $5 million. Facilities include state-of-the-art laboratories and equipment.

The university is a private, heavily endowed, comprehensive university of four thousand students with a strong commitment to teaching and research. Tulsa is an economic and cultural center of 750,000 surrounded by lakes. Applicants should submit curriculum vitae, statement of research, extramural funding plans, and three letters of reference to:

Dr. Steffen Rogers ■ Director, The Mervin Bovaird Center
The University of Tulsa ■ 600 South College Avenue, Tulsa, Oklahoma 74104

The University of Tulsa has an Equal Opportunity/Affirmative Action Program for students and employees.

(NW4499)A

THE INSTITUTE OF CANCER RESEARCH

(University of London)

Sutton, Surrey

SCIENTIFIC OFFICER

MEDICINE

A Scientific Officer is required to work on a project to investigate the use of the polymerase chain reaction to detect micrometastatic disease in lymphocytic lymphoma and myeloma, which will be an integral part of the clinical programmes for these diseases.

The post should provide experience in a wide variety of molecular biology and tissue culture tecnhiques. The research is hoped to create the necessary interface between laboratory and clinical research.

Applicants must hold a degree or equivalent qualification and be able to work as a member of a small team. Experience in molecular biology an advantage but not essential.

Salary will be in the range of £10,447 p.a. to £13,724 p.a. (inclusive). The post is offered initially on a two year contract.

For further information please contact Dr. D. Cunningham tel: 01-643 8901 ext. 3281.

Please forward C.V., in duplicate, with the names and addresses of two referees to the **Personnel Officer, The Institute of Cancer Research, 17A Onslow Gardens, London SW7 3AL** quoting ref no. 10:89.T N 52

Applicants are advised that smoking is prohibited in the majority of the Institute's premises. (2003)A

ERATO

Exploratory Research for Advanced Technology

RESEARCH DEVELOPMENT CORPORATION OF JAPAN

RESEARCH ENGINEERS AND SCIENTISTS: You are invited to COME TO JAPAN to do research at the forefront of basic science and engineering. ERATO, a program fully funded and administered by the Research Development Corporation of Japan, a statutory corporation of the Japanese government, has been inviting non-Japanese researchers to Japan since 1981. ERATO is now seeking researchers for the projects below. (ERATO Projects are directed and funded independently from the project directors' respective parent affiliations).

TONOMURA ELECTRON WAVEFRONT (1989-1994) — Experimental and theoretical physicists, image processing engineers, and biologists will research the basic physics, instrumentation, and applications of electron holography.

Project Director: Akira Tonomura, Chief Researcher, Advanced Research Laboratory, Hitachi, Ltd.

AONO ATOMCRAFT (1989-1994) — Surface scientists, experimental and theoretical physicists and chemists, micromechanical and control engineers, and computer scientists will research the direct manipulation of atoms and molecules on solid surfaces.

Project Director: Masakazu Aono, Chief Scientist, RIKEN (The Institute of Physical and Chemical Research)

IKEDA GENOSPHERE (1989-1994) — Molecular biologists, human geneticists, molecular cytologists, and optoelectronics engineers with interest in the laser measurement of chromosomes will identify, dissect, and analyze human genes relating to cancer and other diseases.

Project Director: Joh-E Ikeda, Chief, Molecular Genetics Laboratory, National Institute of Agrobiological Resources

SAKAKI QUANTUM WAVE (1988-1993) — Solid state physicists, solid state chemists, and semiconductor engineers are researching the fabrication and behavior of quantum wells and wires, structures with features smaller than the electron's mean free path.

Project Director: Hiroyuki Sakaki, Professor, Research Center for Advanced Science and Technology, University of Tokyo

MASUHARA MICROPHOTOCONVERSION (1988-1993) — Electrochemists, physical chemists, applied physicists, and electronic engineers will research the use of lasers to drive, measure and control pico-second chemical reactions in fabricated micrometer-size volumes.

Project Director: Hiroshi Masuhara, Professor, Kyoto Institute of Technology

NISHIZAWA TERAHERTZ (1987-1992) — Solid state physicists, electron physicists, electronic engineers, solid state chemists, and communications engineers are researching the fabrication, behavior, and measurement of semiconductor devices for operation at terahertz frequencies.

Project Director: Jun'Ichi Nishizawa, Professor, Tohoku University, and Director, Semiconductor Research Institute, Sendal

ERATO RESEARCHERS BENEFIT FROM

Well-funded, multidisciplinary research ★ Long-term positions — allowing for significant, in-depth research ★ Industry-competitive salaries ★ Sharing of patent rights ★ Assistance for Japanese language learning (ability in Japanese not required) ★ Cooperative agreements with industry to allow corporate researchers to join

For an independent review of ERATO, see "JTECH (Japanese Technology Evaluation Program) Report on ERATO," National Science Foundation, Dec. 1988 — available from NTIS, 5285 Port Royal Road, Springfield, Virginia 22161 USA, Telephone (703) 487-4826.

Please send your resume and lists of publications and references to ERATO, c/o

MEDICAL RESEARCH COUNCIL
Laboratory of Molecular Biology
Cambridge

RESEARCH ASSISTANT

Applications are invited from research orientated graduates to work in a research group with Dr. Richard Henderson. The research concerns the structure of membrane receptors coupled to G-proteins involved in signal transduction (rhodopsin, ß-adrenergic receptors and related receptors). These molecules all contain seven transmembrane helices and their structure is important for understanding of the action of many existing drugs and for the development of more specific drugs in the future.

Practical work will include membrane receptor protein expression in eucaryotic and procaryotic systems, functional analysis of the products and development of large scale purifications. Candidates will benefit from practical experience in biochemistry and molecular biology.

For more information contact directly Dr Richard Henderson or Dr Gebhard Schertler (phone 0223 248011). Application, including a CV and the names of two professional referees, should be sent by Friday 27 November 1989 quoting reference SS 7196 to:

The Personal Officer,
MRC Laboratory of Molecular Biology,
Hills Road,
Cambridge,
CB2 2QH.

MRC

SCHOOL OF BIOLOGICAL SCIENCES

RE-ADVERTISEMENT

Postdoctoral Research Assistant/Postdoctoral Research Fellow in Molecular Biology

(SALARY R. & A. IB scale :– £9,816–£12,381)
or (R. & A. IA scale :– £10,458–£12,381)

Applications are invited for the above M.A.F.F.-funded post, available immediately and tenable for 3 years. The research will be carried out within the Microbiology and Molecular Biology Research Group in the School of Biological Sciences in collaboration with the School of Agriculture and Forest Sciences.

Candidates should ideally have a background in Recombinant DNA research. The successful applicant will be involved in a major programme (including a grant-funded research technician) using molecular biology techniques to identify the gene(s) determining fertility in sheep.

Salary for Postdoctoral Research Assistant on the R. & A. IB scale within the range :– £9,816–£12,381 or for the Postdoctoral Research Fellow on the R. & A. IA scale:– £10,458–£12,381 depending upon qualifications.

Applications (two copies) giving details of age, education and experience together with the names and addresses of two referees should be sent to **Mr. Alan James, Personnel Officer, University College of North Wales, Bangor, Gwynedd LL57 2DG**, by not later than 17th November 1989. Informal enquiries may be made to Dr. S.J. Assinder, tel. no. (0248) 351151, ext. 2604. (1980)A

Prifysgol Cymru · University of Wales

British Geological Survey

CHEMIST

The Survey has a vacancy for a Chemist in its Fluid Processes Research Group based at Keyworth, Nottingham

The Group is a multi-disciplinary and enthusiastic unit involved in a range of studies into the processes controlling the fate of pollutants in the environment BGS has well-appointed radiochemical and analytical laboratories and requires a chemist with an aptitude for innovative research into a range of environmental problems The successful candidate will initially assist in studying the transport and specification of radionuclides in groundwater and their interactions with mineral surfaces This is presently being approached by the study of natural systems supported by controlled field and laboratory radiotracer experiments

Candidates should have a good honours degree in chemistry preferably with research experience in one or more of the following areas - Electrochemistry, Radiochemistry, Organic Geochemistry (HPLC,GC), Colloid or Surface Chemistry Scientific development and training are encouraged

Salary will be in the range of **£9,131** to **£14,909** according to qualifications and experience Terms include a generous leave allowance and a non-contributory pension scheme The appointment is for a period of three years with the possibility of an extension

The British Geological Survey is a component body of the Natural Environment Research Council

For an application form please write to - Establishments (Recruitment), British Geological Survey, Nicker Hill, Keyworth, Nottingham NG12 5GG Please quote reference SO/FP/89/3 Closing date for completed application forms is 24th November 1989

UNIVERSITY OF GUELPH

Department of Biomedical Sciences

RESEARCH ASSOCIATE

Cryobiology of Mammalian Embryos

An experienced cryobiologist is sought to lead the cryopreservation sector of a research and development program involving the manipulation of bovine embryos The appointment will be for a 4-year term initially

In accordance with Canadian immigration requirements, this advertisement is directed to Canadian citizens and permanent residents of Canada The University of Guelph is committed to employment equity

Applications, including a curriculum vitae and the names of two academic referees, should be sent to **Professor K J Betteridge, Department Biomedical Sciences, University of Guelph, Guelph, Ontario, N1G 2W1** (Tel 519 824-4120, ext 8258, FAX 519 767-1450) before December 31, 1989

(NW4495)A

FACULTY POSITION IN MOLECULAR IMMUNOLOGY
DEPARTMENT OF BIOCHEMISTRY AND BIOPHYSICS
IOWA STATE UNIVERSITY

The department invites applications for a tenure-track position at the level of assistant or associate professor The successful applicant will be expected to develop an independent research program in some molecular aspect of the immune system, possible areas of interest include, but are not limited to, protein chemistry, molecular structure, and molecular genetics The appointee will be expected to have an interest in interacting with existing research programs in the department, to assume moderate teaching duties, and to participate in the interdepartmental Immunobiology Program Generous start-up funds and laboratory space in the new Molecular Biology Building are available Applicants should send curriculum vitae, statement of research plans, and the names and addresses of three references by December 15, 1989 to

Dr Alan M Myers, Department of Biochemistry and Biophysics, 397 Gilman Hall, Iowa State University, Ames, IA 50011

Iowa State University is an Affirmative Action/Equal Opportunity Employer Applications from women and minority candidates are especially encouraged (NW4480)A

University of Freiburg i. Br. (FRG)

Institute of Mineralogy and Petrology

Applications are invited for a post-doctoral research and teaching assistant position (C1) in mineralogy/petrology The 3-years appointment can be extended to a maximum of 6 years The position is available immediately Candidates should have a Ph D degree and a record of significant contributions to the fields of Mineralogy, Petrology or Geochemistry A strong background in physical chemistry and/or computer sciences is desired

The successful candidate will participate in research projects related to fluid/rock interaction processes in the crust

Applications with curriculum vitae and a list of publications should be submitted no later than November 30, to **The Institute of Mineralogy and Petrology, University Freiburg i Br., Albertstr. 23b, D-7800 Freiburg i Br , FRG**

(W6660)A

UNIVERSITY OF SOUTHAMPTON

CRC Wessex Regional Medical Oncology Unit

GROWTH FACTOR PROJECT

Applications are invited for the position of Research Assistant in a group studying the role of polypeptide growth factors in the development and dissemination of cancer

Applicants should have a degree or equivalent in a biological science with a strong background in biochemistry or cell biology Some experience of tissue culture techniques would be an advantage

This is a Cancer Research Campaign funded appointment initially for 2 years, salary range (£9,816–£12,381) according to age and experience

Applications (2 copies) including a full C V and the names and addresses of 2 referees to **Ms J A Doyle, Staffing Department, University of Southampton, Southampton, SO9 5NH,** by 23 November 1989 *Please quote reference number 120/JAD/jm* (1972)A

RESEARCH SCIENTIST

(Environmental Physics)

RESEARCH SCIENTIST/
SENIOR RESEARCH SCIENTIST

A$31,525-A$45,699

Division of Water Resources
CANBERRA AUSTRALIA

GENERAL The CSIRO Division of Water Resources has a staff of 220, including 100 scientists, and conducts research and development into the definition, use and management of Australia's water resources The Division has laboratories in Perth, Adelaide, Canberra and Griffith

As part of research into hydrologic processes at a regional scale, a research group in the Division is concerned with tracing the sources of sediment reaching rivers and water storages This current source tracing uses mineral particle magnetics and radionuclides in catchments up to 56,000 km^2 in area

THE JOB The appointee will join a project team undertaking a number of sourcing investigations in catchments across the country These activities are strongly linked with the needs of soil and water management agencies The appointee will conduct research into the use of natural and anthropogenic radionuclides as tracers of both sediment sources and transit times in large catchments The radionuclides will be used in conjunction with mineral particle magnetics for tracing Communication with government agencies is an important element of the appointee's activities The appointee will be based in Canberra

QUALIFICATIONS A PhD in physics, chemistry or other science is required The appointee must be completely familiar with the principles, operation and use of nuclear electronics, and gamma and alpha high resolution spectrometers He/she must be able to analyse samples for their contents of the natural radioactive decay series, and anthropogenic nuclides The appointee must be able to independently manage all aspects of a radionuclide laboratory, with emphasis on routine high precision low level gamma spectrometry The appointee will also be expected to manage a VG Aqua-Sira mass spectrometer and so familiarity with stable isotope mass spectrometry is desirable Familiarity with the techniques of mineral particle magnetic tracing would be an advantage

TENURE Appointment will be for an indefinite period with Australian Government Superannuation benefits

MORE INFORMATION A job description and selection criteria are available from Mr Geoff Black, CSIRO Division of Water Resources 61 62 46 5213 Questions arising from these may be discussed further with Dr R J Wasson 61 62 46 5665

APPLICATIONS These should be submitted by 17 November 1989, quoting reference number A3135 They should address the selection criteria and include relevant personal and professional particulars including details of formal qualifications and experience Applicants should nominate at least two professional referees, and address applications to

Career Opportunities In Neuropharmacology

Ware, Herts

Does career progression in your current job feel like an obstacle course? If so, then look instead at the benefits of joining a team with a proven track record in a company determined to help you succeed

Glaxo Group Research is Britain's leading pharmaceutical company and as you would expect offers impressive benefits too Whether it's performance-related pay to reward your efforts, or promotion on merit to recognise your abilities, you'll find that we are determined to give you the chance to advance Working in a confident and vigorous research climate may well be what you're missing too

Which ever reason may apply to you, we have the solution - expansion into new areas means that we are seeking graduates for our Neuropharmacology department at Ware This is an excellent opportunity to join a highly productive research group and work with young scientists who lead in their field Some of them studied part-time for a PhD while working at Glaxo - and that opportunity will be extended to you too

If you have up to 3 years relevant experience, preferably in industry, following a degree in Pharmacology or an allied subject we would like to hear from you

Write or telephone for an application form, quoting reference W89221. The Research Personnel Officer, Glaxo Group Research, Park Road, Ware, Herts SG12 ODP. 0920 469469 Ext. 2348

The Department of Neurology at the University of Michigan is seeking applications for a **Research or Tenure Track Position** in Molecular Neurobiology and/or protein chemistry Successful candidate will join a multi-disciplinary team of investigators studying neurotransmitter receptors Position includes laboratory space, start-up funds, and salary support for initial years of program Opportunity exists for a joint appointment in a basic science department Curriculum vitae and three letters of recommendation should be sent to **Robert L Macdonald, MD, PhD, Department of Neurology, University of Michigan, 1108 Neuroscience Bldg , Ann Arbor, MI** 48109-1687 *The University of Michigan is an equal opportunity/affirmative action employer and encourages women and minorities to apply* (NW4503)A

POSITIONS AVAILABLE

The International Laboratory for Research on Animal Diseases (ILRAD), is an internationally funded, major institution with the mandate of developing improved methods to control two important diseases of livestock, trypanosomiasis and theileriosis The multidisciplinary research program includes biochemistry, molecular biology, immunology, cell biology, pathology, parasitology, electron microscopy and entomology with appropriate supporting units Applications are invited for the positions of –

Scientist — Immunology (Ref Sci/89/2)
A position is available to join and supervise a group elucidating the role of T-cells in the induction of immunity to, and the pathogenesis of, *Theileria parva* infections in cattle Studies are carried out both *in vivo* and *in vitro* and include investigation of the role of the bovine Class I, II molecules and the involvement of different T-cell receptors in controlling the specificity of bovine immune responses Candidates will preferably have a first degree in veterinary science, a doctorate in immunology and over five years of post-doctoral experience in ruminant immunology at the cellular level

Scientist — Tick Research (Ref Sci/89/3)
A position to manage the Tick Vector Unit which provides an essential service to the *Theileria* research program The work entails maintenance and supervision of tick colonies, production of infected ticks, sporozoites and theilerial stabilates, supervision and screening of infected cattle and research activities related to immunization of cattle against East Coast fever Candidates must have had experience with ticks and tick-borne diseases Preference will be given to applicants with a first degree in veterinary medicine and a doctorate in a relevant area of parasitology

Research Associate — Immunochemistry (Ref RA/89/2)
A position in immunochemistry is available to support a multidisciplinary reseach group investigating cellular immune responses of cattle to the protozoan parasite, *Theileria parva* The successful candidate will assist in identification of parasite antigens responsible for stimulating T cell responses to parasitised lymphoblasts and to develop antibody reagents which can be used in experiments to isolate and transfect parasite genes The person recruited will also be resonsible for supervision and training of junior technical staff

Applicants should have a science degree or an equivalent diploma in immunological or medical laboratory technology Extensive experience of techniques in protein biochemistry and analysis of antigen-antibody reactions is essential

Research Associate — Immunodiagnostics (Ref RA/89/3)
A research associate position is available in a group involved in the development of improved immunological techniques for the diagnosis of African trypanosomiasis Applicants will have advanced technical qualifications, or a degree in Biochemistry/Immunology with at least 5 years' experience in a senior technical position with supervisory and training responsibilities Consideration will be given only to those applicants with proven abilities in the development and application of immunodiagnostic techniques, and practical experience with antigen and antibody purification procedures, enzyme and other labels, and monoclonal antibody production

These are International staff positions and salary will be paid in US dollars Initial salary will be determined by qualifications and experience Scientific staff are expected to contribute to the training program Moving, housing, commutation and education allowances are paid and there are medical and retirement benefits Applicants should include current curriculum vitae and names and addresses of three referees Applications, citing the position reference number, should be sent by December, 15th 1989 to

The Chief Personnel Officer,
I L R A D,
P O BOX 30709,
NAIROBI
Kenya

UNIVERSITY OF WYOMING
ASSISTANT PROFESSOR
MOLECULAR BIOLOGY

The Department of Molecular Biology at the University of Wyoming has a tenure-track assistant professor position available July 1, 1990 Candidates should have at least two years of postdoctoral experience, will be expected to establish and maintain an active research program, and be involved in teaching at both the undergraduate and graduate levels Applicants in all areas of molecular biology/biochemistry will be considered although preference will be given to candidates with a biophysical orientation The Department has 15 faculty with active research programs funded by NIH, NSF, DOD, USDA and EPA Salary is competitive

Applications will be reviewed starting January 1, 1990 and continued until position is filled

Applicants should send their curriculum vitae, summary of research plans, and arrange to have three letters of reference sent to **Ivan I Kaiser, Search Committee Chair, Department of Molecular Biology, Box 3944, University Station, Laramie, WY 82071–3944**

An Affirmative Action/Equal Opportunity Institution (NW4513)A

UNIVERSITY OF THE WEST INDIES
TRINIDAD
BREEDER/GENETICIST

Applications are invited for the post of Breeder/Geneticist in the UWI, Cocoa Research Unit Applicants should have a background in quantitative and population genetics with a sound knowledge of statistics and the use of microcomputers

The appointee will be expected to develop a research programme to study genetic relationships within the international cocoa germplasm collection and to relate these to plant breeding

Salary Scale Lecturer/Research Fellow TT$54,708 to 66,156

Unfurnished accommodation if available at 10% or furnished at 12½% or housing allowance at 20% of pensionable salary

Up to five full economy passages on appointment Study and travel grant Book allowance

Detailed applications naming three referees to registrar, **UWI, St Augustine, Trinidad** Closing date for application 1st December 1989 Details of post sent to all applicants (W6675)A

New York University Medical Center
POSTDOCTORAL FELLOW
Department of Pathology

Funding is available for a postdoctoral position tenable for two years The project involves the study of events that take place during processing and presentation of antigens by antigen presenting cells Emphasis will be placed on tracing the intracellular transport of antigens and characterizing the intracellular compartments involved in processing Suitable candidates will have a background in either cell biology or immunology

Interested applicants should submit a curriculum vitae including the names and addresses of two references to **Dr Stephanie Diment, Department of Pathology, New York University Medical Center, 550 First Avenue, New York, NY 10016** (NW4505)A

THE DAVID MAHONEY INSTITUTE OF NEUROLOGICAL SCIENCES (INS)

of the University of Pennsylvania invites applications for a tenure track position in systems neurobiology at the rank of **Assistant Professor** Ideally, the candidate should be working at the tissue level, perhaps with a "slice" preparation, and should be able to interact with and strengthen our current substantial representation in research on vision and learning and on neural development Candidates should (by 12/15/89) send a curriculum vitae, a statement of current research interests, and the names of three individuals willing to provide letters of evaluation to **Professor Peter Sterling, Systems Neuroscience Search, Department of Anatomy, University of Pennsylvania, Philadelphia, PA 19104-6058** EEO/AA Employer

BASIC BIOMEDICAL FACULTY POSITIONS

Three faculty positions at the Assistant or Associate Professor level are available effective Feb 1, 1990 in several departments associated with the newly organized Division of Cellular and Molecular Medicine at the University of California School of Medicine at San Diego

Areas of research interest include — but are not restricted to 1) processing, packaging and transport of primary gene transcripts, 2) control of protein and membrane traffic in eukaryotic cells, and 3) eukaryotic cell response to tissue growth factors Other promising fields of research will also be considered

Each applicant is expected to establish an active individual research program but interactions and collaborations with other faculty members of the Division or School will be welcome Each applicant is also expected to participate actively in teaching and research training of medical and graduate students

For candidates for an Assistant Professor position, an M D, Ph D or M D-Ph D degree, at least two years of postdoctoral training, and a strong record in well-organized research are expected Candidates for an Associate Professor position are expected to have already achieved an outstanding record in their field of research Rank and salary determined by qualifications and UC pay scales

Applications supported by a curriculum vitae, a list of publications, a summary of research planned for the immediate future and a list of 5 to 6 potential referees should be sent by February 1, 1990 to

George E Palade, M D
Dean Designate for Scientific Affairs
UCSD School of Medicine (M-002)
La Jolla, CA 92093-0602

UNIVERSITY OF LEICESTER
POSTDOCTORAL RESEARCH ASSOCIATE IN ORGANIC CHEMISTRY

Applications are invited for a post-doctoral position, supported by Pharmachemie B V of Holland, to start as soon as possible The work will involve studies on the chiral synthesis of taxane natural products Applicants should have experience in and enthusiasm for the field of organic synthesis The appointment will be for one year on the RA IA salary range £10,458–£16,665 with a starting point depending on age and qualifications

Applicants should send a c v to **Dr P R Jenkins, Department of Chemistry, University of Leicester, Leicester LE1 7RH,** (tel 0533 522124) as soon as possible and they should ask two referees to write directly to him on their behalf
(2011)A

Senior Scientists in Biomedical Science — Kanagawa, Japan

We invite applications and/or nominations for the positions of senior scientists of the Institute for Biomedical Science The Institute, now being reorganized, will consist of four divisions and we call candidates for the following three divisions

1. Division of Molecular and Cell Biology
2. Division of Bioengineering and Biomedical Materials
3. Division of Artificial Organs and Organ Transplantation

The Institute is one of the three Centers constituting the parent center, Terumo R & D (Director General Tetsuzo Akutsu, M D , Ph D and 500 researchers) The new R&D building (44,146 sq meter) is under construction and will be open in December, 1989 It is located in the town of Nakai, Kanagawa Prefecture, one-hour drive away from Tokyo The town is situated on one of the best geographical environments to live in Japan with an excellent view of Mt Fuji in the west and Sagami Bay in the south

TERUMO CORPORATION is a leading manufacturer with an extensive product lineup including artificial organs, pharmaceuticals, transfusion and infusion products, medical electronics, labo products and medical disposables Terumo has manufacturing R&D and distribution facilities in Japan, U S A , Belgium and Australia

QUALIFICATIONS include a Ph D , and at least seven-year experience in one of the three above-described specialized areas, and an excellent record of scientific achievement Successful candidates will have a chance to be promoted to the Division Chief, who is expected to have supervisory responsibilities directing junior staff

SALARY will be commensurate with experience and qualifications We offer house accommodation, and benefits package together with the opportunity to work in our newly constructed superb facilities equipped with modern technologies

A letter of application, C V , list of publications, three professional referees, and your portrait should be sent by the end of November, 1989 to the following address

Yutaka Tomita, Managing Director,
Technical R & D Division,
Terumo Corporation,
44-1, 2-chome, Hatagaya,
Shibuya-ku, Tokyo 151, Japan
Phone 03(374)8020, Fax 03(374)7493

Applications will be reviewed continuously until suitable candidates are hired Promising candidates will be contacted for further discussions on the terms of employment contract

(W6595)A

TERUMO CORPORATION

THE FACULTY OF CHEMISTRY AND PHARMACY
Institute of Biochemistry
UNIVERSITY OF MUNICH

Applications are invited for the tenured position of an

ASSOCIATE PROFESSOR (C3) OF BIOCHEMISTRY

The applicant has to present the field both in teaching (lectures, courses) and research He/she should preferentially be working in the area of biochemistry of development or the structure and function of proteins There is an age limit of 52 years (at the date of appointment)

The University of Munich complies with an equal opportunities policy

Applications with the necessary academic qualifications (Ph D , teaching experiences, research record) are to be submitted with a **curriculum vitae, academic records** and **list of publications** to the **Dekan der Fakultat fur Chemie und Pharmazie, Universitat Munchen, Geschwister-Scholl-Platz 1, 8000 Munchen 22, F R G by January 31, 1990** (W6663)A

University of Pittsburgh

DEAN, GRADUATE SCHOOL OF PUBLIC HEALTH

The University of Pittsburgh seeks applications and nominations for the position of Dean, Graduate School of Public Health The School is one of six schools of the health sciences on the campus of the University and its affiliated hospitals The School enrolls 607 full- and part-time students (375 FTEs), studying for master's and doctoral degrees in the fields of biostatistics, human genetics, epidemiology, community health services, health administration, infectious diseases and microbiology, environmental health, occupational health, and radiation health The Dean is responsible to the Senior Vice President for the Health Sciences The annual expenditures of the School, including sponsored research, are in excess of $22,000,000

Candidates must have had substantial experience in the academic aspects of at least one of the fields of study at a level equivalent to a full professorship and preferably be engaged currently in research pertinent to that field

Nominations or resumes should be
sent before December 31, 1989, to

George M Bernier, Jr , MD

Behavioural Pharmacologist and a postdoctoral research associate in behavioural pharmacology

Akzo, a leading multinational company with headquarters in Arnhem The Netherlands, currently employes over 70 000 people within 350 companies operating in 50 countries A position at the Akzo company means a career at a technologically high developed company with core activities in chemical products, man-made fibers, coatings and health-care products

Organon International B V., one of the 6 companies within the Pharmaceutical division of Akzo, develops and markets medicines for human use The total number of world-wide employees is about 6300, of which more than 1000 are involved in research and development The latter group conducts activities for the programmes Reproductive Medicine, Immunology & Oncology, Cardiovasculars and Central Nervous Systems Within our R & D Laboratories about 120 organic chemists, in several departments, are responsible for the design and synthesis of new drugs in many classes of compounds including peptides, steroids, heterocycles and carbohydrates

In our department for CNS-Pharmacology we need reinforcement of our team with a Behavioural Pharmacologist and a postdoctoral research associate in behavioural pharmacology Our research is aiming for new therapeutic agents for psychiatric and neurological diseases Major research topics in this department are antidepressants, antipsychotics, anti-dementia drugs, nerve growth enhancers, steroids and peptides Modern methods in neurobiology, neurochemistry, electrophysiology and animal behavioural sciences are exploited and kept up to date

We want our research scientists to join the front runners in their area of expertise, as new neurobiological approaches will have to be explored in order to come up with original and effective agents

We need persons with scientific ambitions and will provide them the facilities to enable original contributions to their area of research and to drug development Contract duration for the postdoctoral position which requires work on steroids and behaviour will be of limited duration

Informal inquiries may be made to Dr C L E Broekkamp by telephoning 31-4120-62801/61862

Letters of application accompanied by a full curriculum vitae and a list of publications should be submitted to Mrs W Cove, Personell Officer, Organon International B V, P O Box 20, 5340 BH Oss, The Netherlands

University College Cork

MICROBIOLOGY

Applications are invited for a full-time temporary post in Microbiology The appointment is for one year commencing on 1 January 1990

Preference will be given to a graduate with a PhD degree in Microbiology The duties involve lecturing, project supervision and research

Applicants are requested to forward a curriculum vitae and arrange that two referee's reports be forwarded to **Professor Seamus Condon, Food Microbiology Department, University College, Cork, Ireland** Tel Cork (010-353-21) 276871, ext 2396 *Closing date Friday, 17 November 1989*

(1984)A

THE SWISS INSTITUTE OF ALLERGY AND ASTHMA RESEARCH

is seeking a

POSTDOCTORAL RESEARCH FELLOW

with experience in immunology and cell biology preferably in the field of IgE antibody regulation Specific areas of research include the establishment of human T cell clones, their immunological, biochemical and genetical characterization and the study of cellular interactions

Applications, including a detailed curriculum vitae and naming academic referees, should be sent to **Dr Kurt Blaser, Ph D, SIAF, Obere Strasse 22, CH-7270 Davos, Switzerland**

(W6677)A

DEPARTMENT OF CLINICAL CHEMISTRY UNIVERSITY OF OULU

(WORLD HEALTH ORGANIZATION COLLABORATING CENTRE FOR RESEARCH IN HUMAN REPRODUCTION)

POSITIONS FOR SENIOR RESEARCHERS

The Department of Clinical Chemistry, University of Oulu, Finland, has been designated as a WHO Collaborating Centre for Research in Human Reproduction The laboratory facilities will be enlarged during 1990, and the Centre will act as a training centre for the WHO Special Programme of Research, Development and Research Training in Human Reproduction The central theme in all its activities will be to train scientists from developing countries in reproduction research and the necessary technologies

The Centre in Oulu should master at least the following technologies

- production of monoclonal and polyclonal antibodies, including mass production of monoclonal antibodies
- purification, modification and derivatization of monoclonal antibodies
- development and use of assay methods for steroids, peptides and proteins
- immunohistochemical methods
- techniques of molecular biology
- external and internal quality control of hormone assays

The researchers to be employed should be prepared to work at the bench and perform the necessary administrative duties They may also be needed as temporary advisers for WHO, which may necessitate travelling With a view to assembling such a research group, applications are invited for the following temporary positions

- Assistant Director (annual gross salary FIM 140 000–215 000)
- Two Senior Scientists (FIM 125 000–180 000)
- Scientist (FIM 93 000–135 000)

The assistant director and two senior scientists should hold a Ph D or an equivalent degree and have a substantial record of publications The assistant director should also have experience in leading scientific research The scientist should preferably hold a Ph D or an equivalent degree, but applications from persons with a lower degree are not excluded

Applications should include

1) curriculum vitae
2) list of publications 1980–1989
3) reprints of publications 1985–1989
4) description of the applicant's research interests, especially in the field of reproduction research
5) date when the applicant is available

The appointments are to the end of 1992 The activities of the Centre will be evaluated at four year intervals, when a decision will be taken as to their continuation

Applications should be addressed **Professor Reijo Vihko, Department of Clinical Chemistry, University of Oulu (World Health Organization Collaborating Centre for Research in Human Reproduction) Oulu, SF-90220 Oulu, Finland** (W6676)A

UNIVERSITY OF CAMBRIDGE

POST-DOCTORAL POSITION IN HUMAN MOLECULAR GENETICS

Funded by the Wellcome Trust

Applications are invited for a Post-Doctoral Fellow in molecular genetics to work on human metabolic disease The position is funded for five years and will entail participation in a group primarily concerned with the identification of candidate cDNAs involved in the development of iron storage disorders Pulsed-field gel mapping studies are already underway to identify the disease predisposing locus

Salary range £14,169 to £16,665 per annum depending on age

Applicants, who should have demonstrated their ability to carry out experimental work in a branch of molecular biology or genetics, should send three copies of their curriculum vitae and apply for further particulars to **Professor T M Cox, University of Cambridge School of Clinical Medicine, Addenbrooke's Hospital, Hills Road, Cambridge CB2 2QQ** Telephone (0223) 336864

Tne University follows an equal opportunities policy (1992)A

MEDICAL RESEARCH COUNCIL

COLLABORATIVE CENTRE

The MRC Collaborative Centre was founded in 1986 to act as a link between MRC basic research units and industry At the Collaborative Centre, commercially-oriented research projects are carried out with scientific support from within the MRC and financial support from industrial sponsors The *Antibody Engineering Group* at the Centre works on projects involving the manipulation of immunoglobulins, at the DNA level, to create novel protein molecules for diagnostic and therapeutic applications We currently have two short-term (two-year) openings within this Group

SCIENTIFIC OFFICER We are seeking a scientist with experience in tissue culture techniques and ELISA assays to work on the expression of recombinant antibody genes in mammalian cells The salary will be on the Civil Service Scientific Officer scale which rises to a maximum of £13,738 (inclusive of London Weighting) per annum, with the possibility of additional increments depending on performance to a maximum of £15,909 p a An optional pension scheme providing a 4 5% non-superannuable supplement is available Annual leave is 22 days plus public holidays and 2 5 priviledge days Applicants should possess a first degree, BTEC higher degree, or equivalent qualification

Please telephone for an application form, quoting reference no CC/AE SO1, on 01 959-3666 × 2270, or write to **Ms Frances Griffiths, Personnel Officer, National Institute for Medical Research, The Ridgeway, Mill Hill, London, NW7 1AA**

POSTDOCTORAL SCIENTIST We are interested in someone with experience in protein structure prediction and modelling to assist in the design of novel antibody molecules The salary will be in the range £14,031-£22,119 per annum (inclusive of London Allowance) Starting salary is dependent on experience MRC pension scheme option

Applications including a C V , list of publications, and the names and addresses of two professional referees should be made to **Mr C R Russell, Administrative Manager** at the above address, quoting reference no CC/AE PD1

Informal enquiries about the work of both vacancies may be made to Dr M M Bendig on 01 906-3811

The closing date for both applications is 24th November 1989

The MRC is an Equal Opportunities Employer (1994)A

---

nature

The international journal of science with 500,000 readers throughout the world seeks

A TALENTED BIOLOGIST

Essential qualifications

- A sound education in some field of biology
- A critical and lively interest in science in general
- A sense of literacy

Research experience desirable

Applications are invited from people seeking a career in the communication of science The successful applicant will join the team responsible for assessing and editing biology manuscripts, either in Washington or in London

There will be opportunities for contributing to *Nature* in other ways Research experience in neurobiology or immunology would be particularly welcome, but those with other interests should not be deterred from applying

US applicants should send their *curriculum vitae*, with a detailed account of their education, research experience and literary skills, to the

Editor, *Nature*,
1137 National Press Building,
Washington, DC 20045

by 20 November and be prepared to be interviewed in Washington shortly thereafter

Applications from elsewhere should be sent to the

Editor, *Nature*,
4 Little Essex Street, London WC2R 3LF

by 27 November (1997)A

Head of Training and Organisation

c.£20,000-£22,000

Beckenham, Kent

Wellcome is an internationally renowned pharmaceutical group engaged in the Research, Development, Manufacture and Marketing of human healthcare products.

As part of the development of the Department of International Medical Affairs, we currently seek to appoint a key individual as Head of Clinical Training and Organisation.

This new post will involve the development of training programmes for medical departments in all territories outside the US and Canada in relation to various aspects of Clinical Practice in the industry. In addition, there will be a significant involvement in resource analysis and the development of improved communication with Local Medical Departments. This position offers good opportunity for personal career development.

Working to improve the world's health

- *The Wellcome Foundation Ltd*
- *Major International Pharmaceutical Group*
- *Research Centre at Beckenham*
- *Annual Turnover > £1,250m*
- *An Equal Opportunity Employer*

Wellcome

The successful candidate will be expected to undertake significant international travel and have excellent communication skills. A scientific/medical background and pharmaceutical industry experience are required. Previous involvement in areas such as clinical research or project management would be advantageous.

In addition to an attractive salary, our excellent benefits include 5 weeks' holiday, pension and life assurance schemes, profit share, a subsidised restaurant and first class sports and social facilities.

Please send letters of application to Wendy Hamilton at

MSL Advertising, Recruitment Resources,
32 Aybrook Street, London W1M 3JL.
Please quote reference WH/171.

RESEARCH SCIENTIST AND ASSOCIATE

MOLECULAR AND CELLULAR BIOLOGY

Amgen, a recognized leader in the biotechnology industry, has immediate opportunities for a Research Scientist and a Research Associate to participate in the characterization, cloning and expression of hematopoietic growth factors.

Qualified candidates for the Research Scientist position must have a Ph.D. and a minimum of 2 years' postdoctoral experience in the expression of recombinant protein in mammalian and prokaryotic systems. Research Associate candidates must have a BS or MS and a minimum of one year of experience in molecular biology and tissue culture. Industry experience is highly desirable.

Amgen offers an excellent compensation and benefits package as well as a stimulating and challenging research environment.

Qualified applicants should send a C.V. or resume, including references, in confidence, to:

European Society for Medical Oncology

ESMO FELLOWSHIPS 1990

The European Society for Medical Oncology (ESMO) offers **5 Fellowships** to outstanding young European medical oncologists. The two year-fellowships (30,000 Dollars per year) have to be spent in one acknowledged European institution outside the country of origin of the candidates.

Requirements for the candidates: younger than 35 years, training in medical ongology, ESMO-Membership (or a pertinent request).

Start of fellowships 1st semester 1990
Deadline for submission 1st January 1990

Candidates should send their CV, together with a letter of acceptance of the host Institution and a detailed research project (basic research or clinically related cancer research) to:

ESMO Office,
Via Soldino 22,
6903 Lugano,
Switzerland.

(W6668)E

Protein Crystallographer

Synchrotron Radiation Applied to Protein Crystallography

Synchrotron radiation is the most versatile and powerful source of x-radiation available in the world today It is being used as an essential technique in many scientific disciplines and demands the existence of large - scale scientific centres with their own research and development programmes

One of the world's leading laboratories for this work is located at Daresbury in North Cheshire where we are carrying out research, with academic and industrial colleagues, into fundamental scientific questions, including some of those associated with structural and molecular biology

The Person

The Laboratory needs a person who will take responsibility for the collection and reduction of protein crystallographic data The person appointed will make use of the existing facilities for the work at the Laboratory but will also be able to assist in their development and participate in their use for original research We are looking for someone with practical experience of protein crystallography and who approaches this technique with enthusiasm and organisation Training in the use of synchrotron radiation (if required) will be given by experienced Laboratory staff The minimum qualifications required are a degree or equivalent

Pay

The appointment will be made at the grade of Scientific Officer or Higher Scientific Officer Salaries will be in the range of £9,131 to £14,909 depending on qualifications and experience A fixed term arrangement could be made A contribution towards relocation expenses may be available

If you are interested please contact the Personnel Department for an application form quoting Ref DL/133, Science & Engineering Research Council, Daresbury Laboratory, Warrington WA4 4AD

UM

INDUSTRIAL RESEARCH CHAIR IN FERMENTATION TECHNOLOGY

Applications are invited for a Senior tenured or tenure track appointment effective 1 July 1990 as Industrial Research Professor in Fermentation Technology The Chair has been established through a five year funding program from the Natural Sciences and Engineering Research Council in collaboration with an industrial sponsor The Chairholder will be expected to take the lead in developing a research program in fermentation technology Candidates must have an international status in the field and will be expected to interact in the research and development fields of ABI Biotechnology Inc

The Chairholder will be expected to attract significant research contracts from industry to augment the substantial funding for equipment, research staff, and operating expenses which are available

The applicant should have a Ph D degree and at least ten years of industrial research experience or equivalent education and experience Salary is negotiable The Chair is primarily a research position, and as such teaching loads will be light with the emphasis on graduate student teaching and research

Both women and men are encouraged to apply In accordance with Canadian Immigration requirements, priority will be given to Canadian citizens and permanent residents

Applicants should arrange to have three letters of reference, curriculum vitae, recent reprints and a brief description of present and prospective research forwarded to **P Loewen, Chairman Search Committee, Department of Microbiology, The University of Manitoba, Winnipeg, Manitoba, Canada R3T 2N2**

Applications and/or nominations will be accepted up to the 30th September 1989, or until the position is filled

(NW4520)A

BRITISH HEART FOUNDATION

LECTURER/SENIOR LECTURER BASIC SCIENTIST RESEARCH POSTS

The British Heart Foundation invites applications from post-doctoral research workers to compete for a number of basic scientist research posts (non-clinical) at lecturer or senior lecturer level The research programme need not necessarily relate to cardiology, but should relate to the cardiovascular system in its broadest sense and be undertaken in a university department within the UK

An award would be for a period of five years with the possibility of an extension of not more than a further five years The award reimburses for salary at the appropriate university scale and carries an allowance of up to £10,000 per annum for research expenses

Applicants must be UK citizens, or have worked in the UK for at least the past three years, or must have done so before taking up an appointment overseas The candidate should be aged approximately 28-33 years and should have shown outstanding ability in carrying out original and independent research

Application may be made by the head of department or the candidate with support from the head of department

Application forms and further details (quoting reference N/BS) are available from

Valerie Mason
The Research Funds Manager
British Heart Foundation

FULL-TIME POSITION AS

ASSISTANT RESEARCH CELL and DEVELOPMENTAL BIOLOGIST

PhD in Molecular Biology/Cell Biology

Must have experience in muscle cell culture and in analysis of cell and protein turnover, growth factor cloning, expression, isolation, and characterization, receptor binding, extracellular matrix components isolation and characterization The Candidate will be in charge of a program to define growth factor interactions with matrix components in vitro and in vivo The job is guaranteed for one year only with a possibility for renewal for three years, depending on grant funding Salary range $37,700-$47,100 depending on experience Closing date December 7, 1989 Write to **Dr Richard Strohman, Department of Molecular and Cell Biology, Division of Cell & Developmental Biology, University of California, 351 Life Sciences Addition, Berkeley, CA 94720** The University of California is an equal opportunity, affirmative action employer (NW4528)A

UNIVERSITY OF NEWCASTLE UPON TYNE

Department of Medicine

JUNIOR RESEARCH ASSOCIATE

A Junior Research Associate is required to join a group studying autoimmune thyroid disease The post is funded by a two year MRC project grant on the Grade 1B salary scale £9,816-£12,381 per annum

The project is entitled "The role of TSH receptors on orbital fibroblasts in thyroid associated ophthalmopathy" The post would suit a graduate with a degree in Biochemistry, an interest in Immunology and experience of cell culture would be helpful, but are not essential The work would be suitable for submission for an M Phil degree

Further information is available from Professor Kendall-Taylor Tel 091 2325131 Ext 24635 or bleep 2154 or Dr Perros Tel 091 2226000 Ext 7012 Applications should include a full curriculum vitae together with the names and addresses of 3 referees and should be sent to **Professor Kendall-Taylor, Department of Medicine, Medical School, The University, Newcastle upon Tyne, NE2 4HH** by 17th November 1989

Department of Biochemistry and Genetics

RESEARCH ASSOCIATE

Applications are invited for a one year MRC funded research associate post at either postgraduate or postdoctoral level The project will involve the use of techniques such as site-directed mutagenesis to investigate the main immunogenic region of the nicotinic acetylcoline receptor Experience in recombinant DNA techniques would be an advantage

Salary will be up to £12,381 per annum on either the Grade 1A or 1B salary scale according to qualifications and experience

Applications, including curriculum vitae and the names of three referees should be sent as soon as possible to **Dr N S Millar, Department of Biochemistry and Genetics, The Medical School, The University, Newcastle upon Tyne, NE2 4HH** (Tel 091 2227423)

Sir James Knott

POSTDOCTORAL FELLOWSHIPS

Applications are invited for two Sir James Knott Fellowships, tenable for two years from 1 October 1990 The Fellowships, tenable in any Faculty, are open to persons who appear likely to make a noteworthy contribution to knowledge One of the Fellowships will be reserved for candidates who have not graduated from this University The other will be open to any person, but other things being equal, will be awarded to one who has not taken a first degree as a member of this University The value of each Fellowship is £10,458 in the first year and £11,088 in the second year

Further particulars and application forms (which must be returned by 30 November 1989) may be obtained from the **Registrar (Fellowships), The University, Newcastle upon Tyne NE1 7RU** (1983)A

PHLS CENTRE FOR APPLIED MICROBIOLOGY AND RESEARCH

Division of Pathology

RESEARCH/PRODUCTION ASSISTANT

Required for expanding production team working with immunodeficency viruses The duties of the post are varied and will involve applied research in addition to routine production work Applicants should possess an honours degree in a relevant biological science The post will be graded at Basic Grade Microbiologist

The post is for a fixed term of 2 years, the salary range is £8,255–£11,073 per annum (under review)

National Health Service terms and conditions will apply

Application forms can be obtained from the Personnel Officer, PHLS Centre for Applied Microbiology and Research, Porton Down, Salisbury, Wilts, SP4 0JG Tel Idmiston (0980) 610391 ext 240 to whom completed forms should be returned by 23rd November 1989 quoting post number 0521 (2000)A

PHLS CENTRE FOR APPLIED MICROBIOLOGY AND RESEARCH

DIVISION OF BIOLOGICS

Research Assistant

Is required for the Bacterial Antigens Group to join a team commencing a project concerning the development of a vaccine against group B Neisseria Meningitidis The post is funded by the MRC and is for 1 year initially The duties of the post are to assist in research into the mechanisms of pathogenesis of the meningococcus Applicants should posses either an honours degree in a relevant biological science or a recognised technical qualification, or have suitable technical experience The post will be graded at either Basic Grade Microbiologist or MPT II depending on the qualifications of the successful applicant

Salary (under review) will be in the range £7,378 to £11,824

National Health Service Terms and Conditions will apply

Application forms can be obtained from the Personnel Officer, PHLS Centre for Applied Microbiology and Research, Porton Down, Salisbury, Wilts SP4 0JG Tel (0980) 610391 Ext 240, to whom completed forms should be returned by 23rd November 1989 quoting Post Number 0571

UNIVERSITY OF LONDON, BIRKBECK COLLEGE

SERC CASE AWARD

Applications are invited for this research award between the Chemistry Department, Birkbeck College and the Division of Biotechnology, PHLS Centre for Applied Microbiology and Research

The project is concerned with the molecular basis of gold resistance in bacteria Research training will be provided in areas of chemistry, biochemistry and biotechnology, including the isolation of bacteria and proteins, protein and DNA sequencing and structural studies using high frequency NMR

Enquiries can be made to Dr Peter Sadler, Department of Chemistry, Birkbeck College, University of London, 29 Gordon Square, London WC12H 0PP (Telephone 01 380 7480, or to Dr Michael Scawen, Division of Biotechnology, Centre for Applied Microbiology and Research, Porton Down, Salisbury, Wiltshire, SP4 0JG, Tel 0980 610391

Applicants should possess a first or upper second class honours degree Applications (including a Curriculum Vitae and the names and addresses of two referees) should be sent to Dr Sadler at Birkbeck College as soon as possible

The basic SERC grant will be supplemented by research merits awards (2004)A

UNIVERSITY OF CAMBRIDGE

Department of Botany

POST-DOCTORAL RESEARCH ASSISTANT

Applications are invited for a post doctoral research assistant to wor on a project supported by th S E R C Membrane Initiative, in volving the study of ion channel from plant cells incorporated int artificial planar lipid bilayers Applications are invited fron candidates with experience in ior transport/electrophysiology, o with experience in the isolation o membrane proteins, but who wisl to gain experience of electro physiology In either case th experience need not be with plan cells

The post is available from January 1990, for about 2½ years on the 1A scale The start date negotiable, but should be before June 1990

Informal enquiries and applica tions including a curriculum vita and the names and addresses o two referees should be sent a soon as possible to Professo E A C MacRobbie, Botany School University of Cambridge, Downin Street, Cambridge CB2 3EA (Tel 0223 333943) (1998)A

POSTDOCTORAL POSITION

available immediately, to participate in ongoing study of excitation-secretion coupling in endothelial cells Techniques employed include patch clamp and fluorescent Ca^{2+} indicators Ph D with experience in electrophysiology required Salary in $20,000-$30,000 range commensurate with experience Send CV and names of two references to **Drs D Adams or C van Breemen, Dept of Pharmacology R189, University of Miami School of Medicine, P O Box 016189, Miami, FL 33101** AA/EOE (NW4500)A

DIRECTOR OF SURGICAL RESEARCH

The Mary Imogene Bassett Hospital, affiliated with Columbia University, is seeking an academic general surgeon or general surgeon/subspecialist with research experience to expand the surgical research program, conduct laboratory research, and supervise surgical resident research projects Adequate space and initial support are available Responsibilities will be divided evenly between clinical activities and The Mary Imogene Bassett Research Institute Submit inquiries and CV to **Michael S Gold, MD, Surgeon-in-Chief, The Mary Imogene Bassett Hospital, Atwell Road, Cooperstown, NY, 13326 Telephone (607) 547-3968** (NW4515)A

DIRECTOR
RADIATION THERAPY

Roswell Park Cancer Institute, affiliated with the State University of New York at Buffalo School of Medicine and Biomedical Sciences, seeks to fill the position of Director of Radiation Therapy The successful applicant will direct an active department of Radiation Oncology in a hospital renowned for patient care and cancer research The successful applicant must be board certified in Radiation Therapy and have proven capabilities in patient care, teaching, research and administration Curriculum vitae should be submitted to

Andrew A Gage M.D.
Deputy Institute Director
Roswell Park Cancer Institute

Department of Biochemistry

POSTDOCTORAL POSITION

An SERC funded postdoctoral position is available in the laboratory of Dr B Connolly The research involves the study of protein nucleic acid interactions using the restriction endonuclease and modification methylase Eco RV enzymes It is hoped to delineate the mechanism by which the two enzymes achieve catalysis at specific DNA sequences Among the approaches being used are preparation of modified bases for incorporation into oligonucleotides, oligonucleotide synthesis, protein chemistry, enzymology, site directed mutagenesis and other molecular biology techniques Candidates should have a Ph D and experience in some of these areas The post is available immediately for a three year period, but can be delayed to 1 April 1990

Salary will be between £10,458 and £12,381 per annum, depending on age and experience

Applicants should send a C V and the names and addresses of two referees to **Dr Connolly, Department of Biochemistry, University of Southampton, Southampton, SO9 3TU, U K**, by 23 November 1989 *Please quote reference number 117/JAD/jm* Informal enquiries can be made by telephone (0703–594330) to Dr Connolly (1978)A

University of Glasgow

Department of Pharmacology

Postgraduate Research Assistant

required for one year on a project on adenosine receptors in the nervous system Some experience with electrophysiological techniques or general pharmacological smooth muscle preparation would be an advantage but is not essential It may be possible for the person appointed to register for a higher degree

Starting date to be agreed at a salary of £9,816 per annum, on Research Assistant 1B scale

Applications should be sent to **Professor T W Stone, Department of Pharmacology, University of Glasgow, Glasgow, G12 8QQ** by 30th November, 1989 (2001)A

Postdoctoral Position — Molecular Biology of Oncogenes

NIH/NRC position available for recent Ph D with training in molecular biology to study the structure/function characteristics of nuclear oncogene (see PNAS **86**, 1186, 1989)

Position renewable for one year with starting salary of $28,000 Must be U S citizen Send C V and names of three references to **Dr Herbert C Morse III, Laboratory of Immunopathology, Building 7, Room 302, N I M, Bethesda, MD 20892**

The NIH is an equal opportunity employer (NW4457)A

THE UNIVERSITY OF MELBOURNE

Australia

ICI — MASSON CHAIR OF CHEMISTRY

Applications are invited for the ICI — Masson Chair of Chemistry This is a new Chair created as a result of the recommendations of a recent external review of the School of Chemistry The Chair represents a significant partnership in academic-industrial collaboration between ICI Australia and the University of Melbourne

The appointee will be a distinguished chemist with an international reputation, who will provide leadership in all areas of the School The appointee will be expected to take over the Headship of the School for a period of five years in the first instance In particular, it is anticipated that the new Professor will have the ability to manage the important change of the School from what is currently a federation of three academic Departments to a single School within which the three basic disciplines can flourish The new Chair will be backed by an effective administrative support structure

The base salary is A$63,919 per annum The University is currently examining the question of salary loadings and responsibility allowances

Further information about the position, application procedure, superannuation, travel and removal expenses, housing assistance and conditions of appointment is available from the Registrar, or from Appointments (37087), Association of Commonwealth Universities, 36 Gordon Square, London WC1H OPF All correspondence (marked "Confidential") should be addressed to the Registrar, The University of Melbourne, Parkville, Victoria 3052, Australia (tel [03] 344 7528 Facsimile 344 6897)

Applications close on 15 December 1989

The Council reserves to itself the right to make no appointment or to fill the Chair by invitation at any stage

An equal opportunity employer (W6661)A

INSTRUCTOR-IN-RESIDENCE

Position available immediately

Applicants should have a Ph D with a minimum of 1 year postdoctoral experience and a strong background in lipid biochemistry

Send C V and 3 references to **Dr D L Cinti, Dept Pharmacology, UConn Health Center, Farmington, CT 06032**

An Affirmative Action Equal/Opportunity Employer M/W/H (NW4490)A

CENTRAL BIRMINGHAM HEALTH AUTHORITY IN ASSOCIATION WITH UNIVERSITY OF BIRMINGHAM

WOLFSON RESEARCH LABORATORIES

QUEEN ELIZABETH MEDICAL CENTRE

SENIOR RESEARCH SCIENTIST

(Molecular Biology)

A post doctoral Research Scientist is required to join the Molecular Biology group in the Wolfson Research Laboratories Current work is focused on the development of molecular biological technologies for clinical diagnosis and the application of genetic engineering techniques to modify antibodies and pollen allergens Experience of DNA cloning, sequencing, site-directed mutagenesis and familiarity with hybridisation and polymerase chain reaction is desirable The post involves supervision of associated research staff The post is funded by the Department of Health and is available for 3 years in the first instance

Salary is within the range £11,778–£15,394, under review (Senior Biochemist scale with Whitley Council Conditions)

Candidates are invited to contact Dr M R Walker on 021 472 1311, ext 4544 to arrange a visit to the laboratory

Job description and application form available from Personnel Department, Queen Elizabeth Hospital, Edgbaston, Birmingham B15 2TH Tel 021 472 1311, ext 3003 Job Ref 473

Closing date 23rd November 1989

CHARLES STEWART MOTT DISTINGUISHED PROFESSOR OF SUSTAINABLE AGRICULTURE

Michigan State University College of Agriculture and Natural Resources requests applications and nominations for the Charles Stewart Mott Distinguished Professorship of Sustainable Agriculture This endowed chair will be responsible for establishing innovative programs and catalyzing a campus-wide program of excellence in sustainable agriculture The position has research, teaching and extension responsibilities, with a charge to enrich education programs with a philosophy of sustainable development, conduct research designed to impact agriculture through integration of alternative, traditional and biotechnological management systems, develop programs to design, test and disseminate agricultural technology, and enhance issues of sustainability and service to international agriculture programs

MSU is searching for a scientist and leader with a distinguished record of achievement and interdisciplinary orientation Candidates will need to possess significant research stature and organizational skills We are seeking an agricultural scientist, broadly trained in agronomy, with the ability to interact with faculty from a diverse array of disciplines The position will be tenured in the Department of Crop and Soil Science

Applications for the Charles Stewart Mott Distinguished Professorship of Sustainable Agriculture will be received until January 10, 1990, or until a suitable candidate is identified Applications, nominations and questions should be forwarded to **Dr George W Bird, Chair, Charles Stewart Mott Professor of Sustainable Agric Search Comm, Dept of Entomology, Michigan State Univ, East Lansing, MI 48824, 517-353 8133, Fax 517-353 4354, Telex 650 2247573 MIC**

(NW4494)A

RESEARCH SCIENTIST — IMMUNOLOGIST

DNAX Research Institute, located near Stanford University, has established strong basic research programs combining recent advances in immunology and molecular biology in an academic environment

A staff scientist position is available for an individual with a doctorate degree in an immunological field, and a minimum of three years experience in the generation of antigen specific human T cell clones, antigen processing, T cell activation, and lymphokine production The successful candidate will participate in a continuing program to investigate regulation of allergic specific human IgE synthesis Demonstrated organizational skills and supervisory experience are also required

Salary range $48K-$55K

Responses must be postmarked not later than November 26 1989, to be considered

Interested candidates should sent a curriculum vitae, representative publications, a statement of research interests, and names of three references to

DNAX RESEARCH INSTITUTE
Human Resources Department

UNIVERSITY OF NEWCASTLE UPON TYNE

THE MEDICAL SCHOOL

LECTURESHIPS (2)

DEPARTMENT OF PHYSIOLOGICAL SCIENCES

Applications are invited for two Lectureships (one of five years fixed-term) in the Department of Physiological Sciences Physiological Sciences, together with the Departments of Clinical Biochemistry and Microbiology in the Faculty of Medicine and the Department of Biochemistry and Genetics in the Faculty of Science, form the Cross Faculty School of Biomedical & Biomolecular Sciences The Department is responsible for teaching an Honours Science course in Physiological Sciences, and Physiology in the integrated medical curriculum and to dental students

Applications will be welcomed from suitably qualified candidates in any area of physiology, including cellular and molecular physiology The newly appointed lecturer will be expected to pursue a vigorous research programme and good opportunities exist for modern research in an interdisciplinary environment

The appointments will be made to the Lecturers' Grade A scale (£10,458–£15,372 p a) or Grade B scale £16,024–£20,469 p a) In the case of a medically qualified person, the appointment will be made to the Lecturers' Pre Clinical General Grade (£12,879–£20,874 p a) or to the Lecturers Pre Clinical Higher Grade (£18,690–£21,489 p a) Starting salaries will be according to qualifications and experience

Further particulars may be obtained from the Senior Assistant Registrar, Establishments, The University 6 Kensington Terrace Newcastle upon Tyne, NE1 7RU, with whom applications (3 copies) together with the names and addresses of three referees, should be lodged not later than 4th December 1989 (2013)A

ROWETT RESEARCH INSTITUTE

BUCKSBURN, ABERDEEN, AB2 9SB

VACANCIES IN PROBIOTICS RESEARCH

The Rowett Research Institute is Western Europe's leading centre for studies in nutritional science It is located on the outskirts of Aberdeen and has close links with other prominent educational and research centres in Grampian Region which is one of Scotland's most thriving and attractive areas

A multidisciplinary research group is being established at the Institute to investigate modes of action of probiotics The programme, which is funded by a consortium of companies and the DTI, will run for three years The research group will consist of 6 scientists, together with support staff appointed specifically for this project This group will work in collaboration with a number of existing Institute staff whose expertise is particularly relevant

CELL BIOLOGIST/HISTOLOGIST/ ELECTRON MICROSCOPIST

As the cell biologist in this group you will use microscopic techniques to study microbial binding to mucosal receptors and the effects of dietary and other factors on binding You will work with a biochemist and a microbiologist studying the interactions both *in vivo* and *in vitro* between lectins, glycoproteins and polysaccharides of both dietary and microbial origin, with mucosal receptors of the small intestine and the modulation of binding by dietary sugars and lectins

You should have relevant experience in cell biology and histology and be familiar with modern cytochemical techniques using both light and electron microscopy

MICROBIOLOGIST/IMMUNOLIGIST

As one of two microbiologists appointed to this group you will have responsibility for in vivo microbiology, assessing microbial activity in the digestive tract, evaluating the probiotic effects of indigenous and administered microorganisms You will also have responsibility for studying the immunological aspects of probiosis, assessing the effects of the enteric microflora on the humoral and cell-mediated immune systems

As a candidate for either of these posts you should be self motivated, a good communicator and able to work effectively in a multidisciplinary team Both appointments will be made either at the Scientific Officer or Higher Scientific Officer grade

Salary Range — (SO) £10,678 to £12,223, (HSO) £10,678 to £14,909

Minimum Qualifications — Appointees to the SO grade should have a 1st or upper 2nd class honours degree with at least 2 years relevant post graduate experience for HSO grading

PhD STUDENTSHIP (CHEMIST/BIOCHEMIST)

A PhD studentship is also offered as part of the project, to examine in vitro the sugar specificities of the adhesins of selected potential probiotics and of pathogenic species

This studentship will be administered in accordance with the normal terms of Research Council's studentships except that the maintenance grant will be augmented to £4,500 p a Candidates will be expected to have a 1st or upper 2nd honours degree

Applications for these posts are invited from suitably qualified candidates who should write with full details including a CV and the names and addresses of 2 referees to the Secretary of the Institute Informal enquiries can be made by telephone to Dr Malcolm Fuller, ext 332, or Dr Andrew Chesson, ext 320, both on Aberdeen (0224) 712751

Closing date 24th November 1989 (2010)A

UNITED MEDICAL AND DENTAL SCHOOLS

Division of Anatomy, Guy's Campus

LECTURESHIP IN MOLECULAR NEUROBIOLOGY

Applicants for this post should have experience in molecular biological techniques and an interest in neurobiology The lecturer will be expected to pursue independent research and contribute to undergraduate teaching The appointment will be for 5 years in the first instance Salary on University non clinical Lecturer Scale A £10,458–£15 372 Scale B £16 014–£20 469 plus £1,650 London Weighting Allowance

To discuss the post informally contact Professor M Berry (01 955 4360) or Dr Andrew Lumsden (01 955 4413) For further details phone 01–928 9292 ext 3341 Applications in the form of full curriculum vitae (6 copies) should be sent to the Personnel Officer, UMDS, St Thomas's Campus, Lambeth Palace Road, London SE1 7EH quoting reference G/ANA/419 by 14 November 1989 (1888)A

DIRECTOR OF HIGHER EDUCATION AFFAIRS

Swindon, Wilts

The Natural Environment Research Council wishes to appoint a senior person to be responsible for the formulation and implementation of policies in support of higher education with relevance to environmental research This support includes the provision of research grants, post-graduate training awards and fellowships tenable in higher education institutions, together with scientific services and facilities The total value of NERC's contribution to these areas exceeds £23 million a year The post-holder will play an important role in developing and maintaining links and relations between NERC research activities and the higher education sector, and will be responsible for the effective operation of NERC's peer review system, and for establishing and maintaining detailed overviews of departmental and individual performances

The successful applicant will have a good awareness of current higher education sector activities in the sciences relevant to environmental research, and is likely to be working at present at professorial level in a university or polytechnic The appointment will be for a three year period in the first instance, with the possibility of eventual permanent appointment The post would be ideally suited to a secondment from the higher education sector

Salary will normally be in the range of £30,001 to £33,991 per annum, but a higher salary may be available for a candidate with special qualifications or experience.

A non-contributory pension scheme is available, along with a generous annual leave allowance

The post will be located at NERC's Headquarters in Swindon, Wiltshire, and is likely to require a significant amount of travel throughout the UK Assistance towards relocation expenses may be payable in certain circumstances

Application forms can be obtained from June Shields, Personnel Section, Natural Environment Research Council, Polaris House, North Star Avenue, Swindon, Wilts SN2 1EU Tel 0793 411695

Completed application forms including a full CV to be returned by 24th November 1989

MRC LABORATORY OF MOLECULAR BIOLOGY

The following PhD projects are available for studies commencing in October 1990 A limited number of MRC studentships, subject to the usual eligibility requirements, will be offered on a competitive basis These studentships can be supplemented by up to £500 p a for students with additional laboratory responsibilities

Dr B Barrell	Development of computer programs to analyse large DNA sequences
Dr A Bloomer	Crystallographic studies of protein assemblies
Dr P Evans	Crystallographic studies of allosteric and catalytic mechanisms of phosphofructokinase
Dr R Henderson	Structural analysis of photochemical intermediates and mutants of bacteriorhodopsin
Dr R Kay	Molecular basis of intercellular signalling controlling cell differentiation and patterning in *Dictyostelium*
Dr J Kendrick-Jones	Probing the role of myosin type 'motors' in cell motility using protein engineering, cell biological and biochemical approaches
Dr J Kilmartin	Biochemistry and genetics of yeast mitosis
Dr G Koch	Structural studies on luminal ER proteins
Dr P Lawrence	Developmental genetics of *Drosophila*
Dr A Leslie	Structural studies of mutants of chloramphenicol acetyltransferase
Dr A McLachlan	Maximum entropy in crystallography Structure and sequence analysis of proteins
Dr B Pearse	Coated vesicles, adaptors and sorting
Dr H Pelham	Targeting of proteins to their correct locations in yeast and animal cells
Dr T Rabbitts	Studies of developmentally regulated oncogenes
Dr D Rhodes	Structural studies on DNA-binding proteins and their interactions with DNA
Dr A Smith	Site-directed modification of germ-line immunoglobulin genes by homologous recombination
Dr M Stewart	Molecular interactions and assembly dynamics of nuclear envelope components studied using directed mutagenesis and expression of cDNA
Dr A Tomlinson	Molecular genetics of *Drosophila* eye development
Dr A Travers	Nucleic acid structure and biological function
Dr J Walker	Genetic and structural studies of mitochondrial respiratory enzyme complexes
Dr J White	Cellular differentiation during the early development of *Caenorhabditis elegans*
Dr M Wilcox	Molecular and genetic analysis of *Drosophila* integrins
Dr D Zimmern	Studies on the function and expression of the proteins and ribozymes of two RNA viruses

International Research Fellowship Opportunities

for U.S and Foreign Postdoctoral Scientists

*Senior International Fellowships

These fellowships offer opportunities to U S biomedical, behavioral, or health scientists to conduct research in a foreign institution The program is for scientists who have established themselves in their chosen career in the United States and whose professional stature is well-recognized by their peers and institution officials

The purpose of this program is to enhance the exchange of ideas and information about the latest advances in the health sciences, basic, clinical, and public health and to permit U S scientists to participate abroad in ongoing study or research in foreign institutions

Fellowships are awarded for a period of 3 to 12 months and provide stipend, travel, and living allowance

*International Research Fellowships

These fellowships offer opportunities to foreign scientists in the formative stage of their career to extend their research experience in U S laboratories Selections are first made by the Nominating Committee in participating countries, regions, or areas Over 50 countries or regions in the Americas, Africa, Europe, Asia and the Far East, plus Australia, and New Zealand participate in the program

The purpose of this program is to forge relationships between distinguished scientists in the United States and qualified scientists in other countries in order to study health-related problems of mutual interest

Fellowships are awarded for a minimum of 12 months and provide stipend, travel, and institutional allowance

*Foreign-Supported Fellowships

These fellowships for U S scientists are supported by specific foreign countries and areas They provide opportunities for scientists to conduct collaborative research in the country that provides funding

The purpose of this program is to enhance the exchange of research experience and information in the biomedical, behavioral, and health sciences The maximum period of support for all programs is 1 year, and the minimum period of support varies with each program

Participating countries and areas are FINLAND, FRANCE, FEDERAL REPUBLIC OF GERMANY, IRELAND, ISRAEL, JAPAN, NORWAY, SWEDEN, SWITZERLAND, and TAIWAN

**Health Scientist Exchanges

These programs for U S scientists support short- and long-term visits to AUSTRIA, BULGARIA, HUNGARY, POLAND, ROMANIA, the SOVIET UNION, and YUGOSLAVIA

The purpose of these programs is to conduct collaborative activities in one of the health sciences or the health-related fields that are of mutual benefit to the United States and the participating country Priority is given to visits designed to strengthen or expand ongoing collaborative relationships or to explore prospects for long-term cooperation

The financial provisions include round-trip travel and in-country costs

*AIDS Fellowships

There are two programs to support scientists interested in AIDS research The postdoctoral fellowship program supports U S and foreign scientists to conduct research abroad and in the United States, respectively The minimum support is for 3 months, and the maximum support is for 24 months Institutional awards have been made to four U S institutions for a 5-year period

The epidemiology training grants provide long-term training which may lead to the M S or Ph D degree and short-term training in the United States or participating foreign countries Only foreign scientists from developing countries may participate in this program Institutional awards have been made to ten U S institutions

The financial provisions of these programs include stipend, travel, and a host institutional allowance

---

*Requests for additional information on Senior International, International Research, Foreign-Supported Fellowships, and AIDS Fellowships should be sent to International Research and Awards Branch, John E Fogarty International Center, National Institutes of Health, Bethesda, MD 20892

**Requests for additional information on Health Scientist Exchanges should be sent to International Coordination and Liaison Branch, John E Fogarty International Center, National Institutes of Health, Bethesda, MD 20892

Applications are invited for the above post which is available immediately

Candidates should have a PhD in biochemistry, immunology or a related subject, together with suitable postdoctoral experience and will be expected to establish a research team working in the application of molecular biology, biochemistry or immunology to medicine

Salary on the scale for Lecturer Grade A (£10,458–£15,372) or exceptionally Grade B (£16,014–£20,469) according to qualifications and relevant experience

Informal enquiries may be made to Professor Whicher (tel 0532 335673)

Application forms and further particulars may be obtained from and completed applications forwarded to the **Registrar, The University, Leeds LS2 9JT** (tel 0532 333969) quoting reference no 84/24 *Closing date for applications 22nd December 1989*

MISCELLANEOUS

IN AUTO IMMUNE disease,if th disease commences as a singl event affecting a single cell even affecting a single cell and propa gates by positive feedback it i likely that the immune reactio releases more antigen —Reply t Box No 1968J c/o Nature, 4 Little Essex Street, London WC2R 3LF (1968)J

NATO ADVANCED STUDY INSTITUTE

"THE APPLICATION OF CHARGE DENSITY RESEARCH TO CHEMISTRY AND DRUG DESIGN"

17-27 April 1990

Costa Brava, SPAIN

The aim is to instruct in the methods of Charge-Density analysis by X-ray and neutron diffraction and to explore the use of this information in chemistry and drug design

Information and application forms can be obtained from the directors

G A Jeffrey
Department of Crystallography,
University of Pittsburgh,
Pittsburgh, PA 15260, U S.A.

In Situ Hybridisation Course

23rd–27th April 1990

This one week course provides an introduction to the most important concepts and procedures of *in situ* hybridisation The course consists of a lecture programme designed to illustrate the theoretical aspects and recent applications in different fields, including pathology, virology and neurobiology There will be a practical session which will cover all aspects of the technique

Topics covered will include

- Construction and labelling of single and double stranded RNA and DNA probes with radiolabels and biotinylated nucleotides
- Tissue handling and collection, including cytological preparations
- Fixative choice and tissue processing
- Pre-hybridisation treatments and probe choice
- Optimisation of conditions for hybridisation and post-hybridisation stringency washes
- Visualisation systems using autoradiography or chomogenic methods
- Quantification of reaction product
- Analysis of results and troubleshooting

Course organisers	Professor Julia M Polak, Dr S J Gibson and Dr G Terenghi (Histochemistry)
Course fee (inc catering)	£400 full course (inc practicals) £240 lectures only
Further details and application forms from	Wolfson Conference Centre Royal Postgraduate Medical School Hammersmith Hospital Du Cane Road London W12 0NN
Telephone 01 740 3117	
Closing date for applications	15 January 1990

Late applications will be accepted on a space-available basis (NW4389)C

Royal Postgraduate Medical School

(University of London)

Immunolabelling for Electron Microscopy

8th–12th January 1990

A one-week course which will include lectures and practicals

Speakers include.

- Julian Beesley
- John Priestley
- Brian Causton
- Giselle Hodges
- Bharat Jasani
- Geoffrey Newman
- David Hopwood

The course will cover.

Preparation and processing of tissue
Pre- and post-embedding immunohistochemistry
Colloidal gold techniques
Cryoultramicrotomy
Multiple staining procedures

Course organisers

Dr C Sarraf (Histopathology)
Professor J M Polak (Histochemistry)
Dr A Merighi (Histochemistry)

Course fee (inc catering) £350 00

MOLECULAR ENDOCRINOLOGY AND TECHNIQUES FOR HORMONE ACTION

February 18–22, 1990

This course will consist of lectures in methodology with comprehensive syllabus covering receptors, gene transcription, mRNA and protein synthesis, recombinant DNA, protein hormones and cyclic nucleotides

Co-directors M R Hughes and B W O'Malley
Fee $365 ($245 fellows and students)
For further information contact **Bonnie Cuthbert, Department of Cell Biology, Baylor College of Medicine (713)-798-6200**
DEADLINE—February 2, 1990 (NW4144)C

STUDENTSHIPS

ST MARY'S HOSPITAL MEDICAL SCHOOL

(a constituent College of Imperial College of Science, Technology and Medicine)
(University of London)
Norfolk Place, LONDON W2 1PG

DEPARTMENT OF PHARMACOLOGY AND TOXICOLOGY

PhD STUDENTSHIP

Available immediately for 3 years in the above department to join an existing team studying the fate of nitrogen-containing compounds and their relationship to human disease

Applications, in the form of a full C V with names and addresses of 2 referees should be submitted as soon as possible to **Dr S C Mitchell** at the above address (1962)F

RESEARCH STUDENTSHIP IN ANIMAL BEHAVIOUR

Applications are invited for a postgraduate scholarship to study behaviour in poultry The scholarship is tenable for 3 years, is funded by the British Egg Marketing Board Research Education Trust and will lead towards a Ph D degree The subject will be The effect of housing on spatial and fear behaviour in laying hens

The research will be carried out mainly at the Edinburgh Research Station of the AFRC Institute of Animal Physiology and Genetics Research with Dr B O Hughes and Dr M C Appleby and form part of a major resea programme into farm ani physiology, behaviour and v fare Some field work may ta place at the West of Scotla College, Ayr

Applicants should posses a Firs Upper Second Class Hono Degree in Zoology, Agriculture a related subject and should sen CV, together with the names two referees to Dr B O Hugh AFRC Institute of Animal Phy ology and Genetics Resear Roslin, Midlothian EH25 9 Closing date November 30, 198

(2002)

Comisión Interministerial de Ciencia y Tecnología

Research in Spain.

The Spanish Ministry of Education and Science is encouraging foreign national researchers, by means of grants/scholarships, to spend time in Spain to pursue research projects in universities and research centers.

Grant announcement for Ph.D's who have read their doctoral dissertation within the last seven years:

Application deadline date May 31, 1990
Beginning date Last quarter of 1990,
Exceptionally, other dates may be considered
Grant duration Six months to two years

Grant announcement for researchers on sabbatical leave:

Application deadline date December 31, 1989
Grant duration Three to twelve months

INFORMATION AND APPLICATION FORMS:

(W6674)H

AWARDS

THE 1990 LOUISA GROSS HORWITZ PRIZE

The Louisa Gross Horwitz Prize was established under the will of the late S Gross Horwitz through a bequest to Columbia University, and is named to honor the donor's mother Louisa Gross Horwitz was the daughter of Dr Samuel David Gross (1805–1889), a prominent surgeon of Philadelphia, and author of the outstanding "Systems of Surgery" who served as president of the American Medical Association

Each year, since its inception in 1967, Columbia University has awarded The Louisa Gross Horwitz Prize for outstanding basic research in the fields of **Biology or Biochemistry** The purpose of this award is to honor a scientific investigator, or group of investigators, whose contributions to knowledge in either of these fields is deemed worthy of special recognition

The prize consists of an honorarium and a citation which are awarded at a special presentation event Unless otherwise recommended by the Prize Committee, the prize is awarded annually The 1989 awardees are Dr Alfred G Gilman of the University of Texas, Southwestern Medical Center School at Dallas and Dr Edwin G Krebs of the Howard Hughes Medical Institute Research Laboratories, University of Washington School of Medicine in Seattle

QUALIFICATIONS FOR THE AWARD

The Prize Committee recognizes no geographical limitations The prize may be awarded to an individual or a group When the prize is awarded to a group, the honorarium will be divided among the recipients, but each member will receive a citation Preference will be given to work done in the recent past

Prospective recipients should be nominated to the Chairman of the Horwitz Prize Committee, Dr Samuel C Silverstein Nomination letters should include

1 A summary, preferably less than 500 words, of the research on which this nomination is based
2 A summary, preferably less than 500 words, of the significance of this research in the fields of biology or biochemistry
3 A brief biographical sketch of the nominee, including positions held and awards received by the nominee
4 A listing of up to ten of the nominee's most significant publications relating to the research noted under Item 1
5 A copy of the nominee's curriculum vitae

Send to Dr Samuel C Silverstein, Department of Physiology & Cellular Biophysics, Columbia University, 630 West 168th Street, New York, New York 10032

Deadline for receipt of nominations is January 4, 1990 (NW4482)N

THE MICHELSON-MORLEY AWARD

The prestigious Michelson-Morley Award is presented by Case Institute of Technology to recognize the distinctive achievements of a particular scientist or engineer The award is named in honor of Albert A Michelson, first professor of physics at Case Institute and 1907 Nobel laureate, and Edward W Morley, distinguished professor of chemistry at Western Reserve College Joint research by Professors Michelson and Morley is highlighted by their experiments related to the velocity of light These scientific probes prepared the way for the discoveries of Albert Einstein and decisively advanced modern theoretical physics

The stated purpose of the award is to honor the individual chosen for eminent contributions to knowledge and to the well-being of mankind, to perpetuate the tradition of scholarly inquiry exemplified by the independent and collaborative research of Professor Michelson and Morley, and to call to the attention of the general public the continuing contributions of the scientist and engineer to human welfare Deadline for nominations 15 November 1989

Nominations should be sent to **Glenn R Brown, Dean of the College, Case Western Reserve University, Crawford Hall #7100, 10900 Euclid Avenue, Cleveland, OH 44106** (NW4486)N

HE CARE TO MEET, TO KNOW, TO UNDERSTAND

Ares-Serono Symposia is an independent foundation, created in 1971, to promote scientific research in all disciplines which contribute towards improving human health. This aim is pursued by means of congresses, courses, seminars and specialized studies.

ome of the international meetings scheduled for 1990 are:

tokines: Basic Principles and nical Applications
orence / March 26-28
ientific Organization: A.K. Abbas SA) and S. Romagnani (I)

ormonal Communicating Events the Testis
ome / April 9-10
ientific Organization: M.L. Dufau SA) and A. Isidori (I)

eproduction, Growth and evelopment. V Pan-American ongress of Andrology
capulco / April 23-25
ientific Organization: A. Negro-Vilar SA) and G. Perez-Palacios (MEX)

Computers in Endocrinology
Milan / May 7-10
Scientific Organization: V. Guardabasso (I), G. Forti (I) and D. Rodbard (USA)

Major Advances in Human Female Reproduction
Rome / May 10-12
Scientific Organization: E.Y. Adashi (USA) and S. Mancuso (I)

The New Biology of Steroid Hormones
Budapest / September 3-4
Scientific Organization: F. Naftolin (USA)

Endocrinology Under 35
Siena / October 8-10
Scientific Organization: M. Maggi (I)

Plasminogen Activators: from Cloning to Therapy
Florence / October 29-31
Scientific Organization: T. Astrup (DK) and G.G. Neri Serneri (I)

IV Conference on Differentiation Therapy
Yamanashi-ken, Japan / November 4-9
Scientific Organization: G.B. Rossi (I), F. Takaku (J) and S. Waxman (USA)

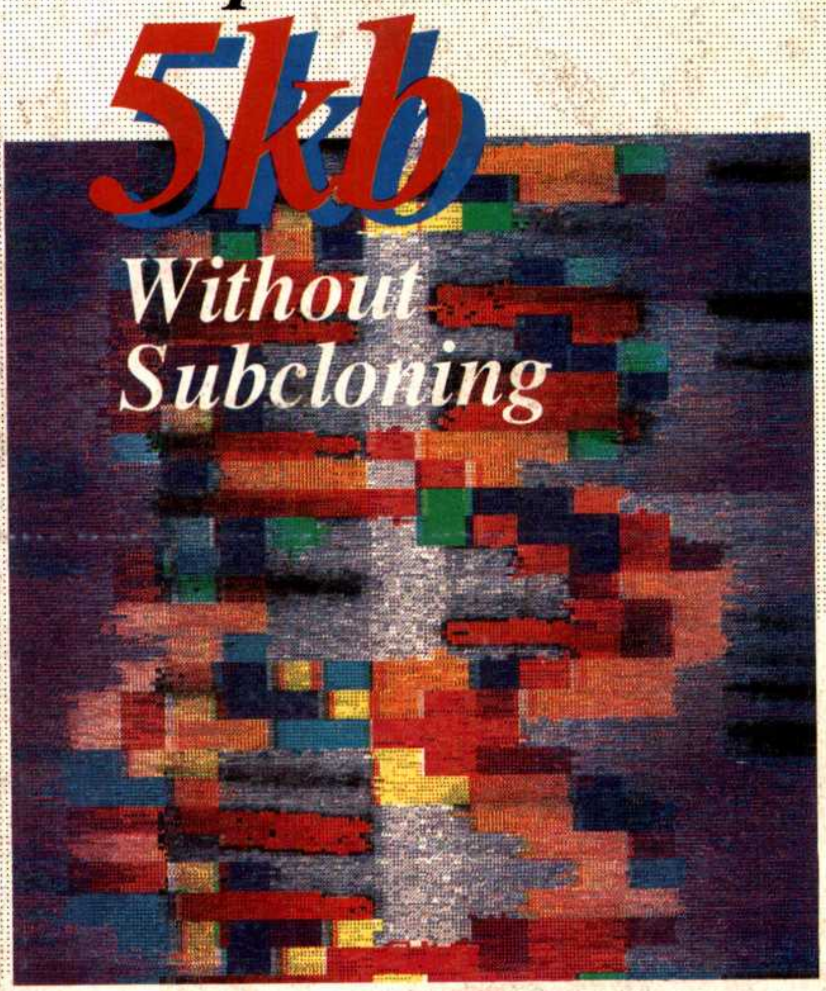
Sequence 5kb Without Subcloning



Introducing the ExoMeth™* Sequencing Kit from Stratagene

- New Method for Sequencing DNA Utilizing 5-methyl dCTP
- A Revolutionary Sequencing Paradigm - 10 Fold Faster
- No Minipreps
- No Restriction Mapping Necessary
- No Oligonucleotides
- No Mung Bean or S1 Nuclease
- No Transformations
- Ordered Strategy, No Shotgunning
- Utilizes Double Stranded Templates
- Utilizes T7 DNA Polymerase or Reverse Transcriptase

Contact Technical Services for Stratagene's ExoMeth™ Sequencing brochure.

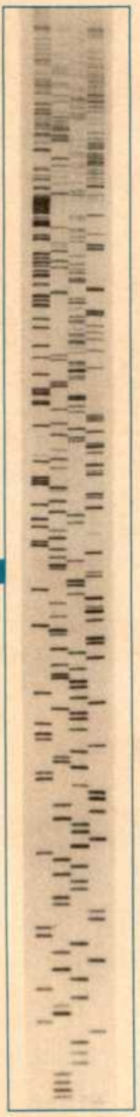
USBIOCLEAN™

DNA can be purified by glass adhesion easily and quickly with the new USBioclean™ DNA preparation kit.



Sequence produced by dideoxy-sequencing with Sequenase®* Version 2.0 of a double-stranded plasmid prepared with USBioclean™ Details of the plasmid preparation are described in Vol. 16, No. 3 of *Comments*, available upon request.

*Sequenase® T7 DNA Polymerase. Patent No. 4,795,699. Patents pending in U.S. and other countries.

USBioclean™ utilizes high quality glass powder for rapid concentration of DNA, desalting of DNA, extraction of DNA from agarose, and removal of organic solvents from DNA. In addition, isolation of plasmid DNA from minipreps and separation of labeled DNA from unincorporated nucleotides can be performed, simply and inexpensively. After purification using USBioclean™, DNA can be successfully modified with many enzymes.

When using any glass adhesion method for isolating DNA, it is important to note that the use of TBE buffer (Tris-Borate-EDTA) can inhibit the ability of DNAs to bind to glass, thus lowering recovery efficiency. For this reason, concentrated TAE buffer (Tris-Acetate-EDTA) is included in the USBioclean™ kit, assuring a convenient method with the highest recovery from agarose gels.

In addition to TAE buffer concentrate, the kit includes sufficient reagents to clean approximately 500μg of DNA isolated under a variety of conditions.

Look to USB for innovative and convenient research kits, as well as unsurpassed quality and service in the supply of more than 6,000 biochemical products.

USBioclean™
Product No. 74000
1 Kit $80.50

Detecting nucleic acids with light

ECL gene detection system
(enhanced chemiluminescence)

The ECL gene detection system is a sensitive, easy to use nucleic acid labelling, hybridization and detection system that uses light (enhanced chemiluminescence) as the detectable signal.

- **Rapid, simple labelling** – Direct labelling of probes with horseradish peroxidase (HRP) takes place in a single tube reaction in 20 minutes.
- **Easy reprobing** – Because of the nature of the signal, blots can be reprobed immediately without removing the original probe.
- **High sensitivity** – Single copy gene detection on Southern blots. Sensitivities of 1pg are easily achievable in all nucleic acid blotting applications using both nylon and nitrocellulose blots.
- **Fast results on film** – In the presence of the detection reagent, the HRP labelled probe emits light (enhanced chemiluminescence) which is detected on film within 1 hour.
- **Convenience** – Each kit contains the essential reagents for labelling and detection of nucleic acids including an optimized hybridization buffer and step by step protocols, in a modular format which gives you improved flexibility.

nature

16 November 1989

Vol. 342 Issue no. 6247

◀ Social insects like these female *Polistes bellicosus* wasps reproduce indirectly — most individuals achieve genetic success by helping to rear offspring of colony mates. But in species not divided into morphological castes, sacrifices are made only for rather close relatives. See page 268. Autumn Books, pages 303–326.

THIS WEEK

Ozone hole spreads

Airborne measurements taken during August and September 1987 show that there was high-latitude ozone loss outside the Antarctic ozone hole. So not only is the geographic extent of the ozone loss larger than generally thought, but ozone is lost earlier in the year than previously reported, pages 233 and 225.

Second-hand gene?

The structure of the *E. coli* 'chaperonin' protein PapD, which prevents pilin subunits from aggregation and degradation prior to their assembly into pili at the outer membrane, shows it to comprise two domains, each with the characteristic immunoglobulin fold. Together with sequence similarity to a lymphocyte differentiation antigen this suggests *E. coli* may have acquired *PapD* by gene transfer from a eukaryotic host. Pages 248 and 224.

Extraterrestrial primer

Did extraterrestrial organic molecules play a role in prebiotic evolution on Earth? On page 255, E. Anders calculates that a substantial amount of organic matter from comets and asteroids did survive atmospheric entry to reach the Earth's surface, primarily carried by small particles associated with the last stage of the period of heavy meteoritic bombardment.

Building bridges

Methods of increasing protein stability without reducing enzymatic activity will make it possible to use enzymes in a wider range of industrial processes. On page 291 it is shown that the melting temperature of a protein, T4 lysozyme, can be increased by as much as 23°C when three additional disulphide bonds are introduced by site-directed mutagenesis.

No link to depression

Further analysis of the Amish pedigree in which linkage of manic depression to a locus on chromosome 11 has been reported reduces the evidence for linkage to below statistical significance. Pages 238 and 222.

Tunnel vision

Negative differential conductivity, until recently seen only in macroscopic electronic devices such as tunnel diodes, can be obtained on an atomic level by use of a scanning tunnelling microscope, page 258. The recent achievement of large-scale integration of STMs on a silicon wafer suggests that the microscopic tunnel diode could be incorporated in a practical device.

Attractive proposition

The discovery of galactic streaming motions of up to 600 kilometres per second towards the constellations of Hydra and Centaurus led to the suggestion of a 'Great Attractor', a concentration of galaxies causing the motions. A new survey of galaxies in this region fuels the debate on large-scale motions, page 251.

Taking the strain

Radiotelemetry has been used to monitor the strain on the limb bones of gibbons in their natural habitat, the forest canopy. The data reveal greatly reduced bending and compressive forces in comparison with other mammals, contributing to the evolution of the long slender forelimb bones of 'brachiating' mammals. Pages 270 and 229.

Crossed lines

What links deep-sea noises, thunder claps and amorphous semiconductors? See page 223.

Author Index

The Author Index to Vol. 341 follows Autumn Books. Guide to Authors faces page 1 of index.

Nature® (ISSN 0028-0836) is published weekly on Thursday, except the last week in December, by Macmillan Magazines Ltd (4 Little Essex Street, London WC2R 3LF). Purify DNA from TBE or TAE Agarose Gels in 20 Minutes

with the

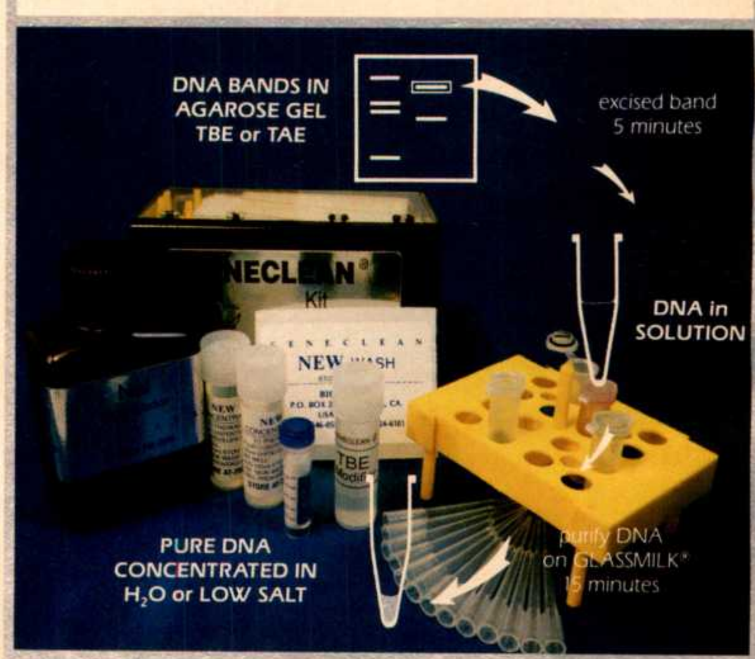
GENECLEAN® *II*

Kit

- ☑ **REMOVE AND PURIFY DNA FROM AGAROSE GELS FAST . . .** 20 minutes from Gel-Band to purified DNA in water or TE. And with **GENECLEAN® II** you can use TBE buffers.
- ☑ **REMOVE EXCESS LINKERS, PCR PRIMERS, UNREACTED LABELLED NUCLEOTIDES and/or DESALT AND CONCENTRATE DNA SOLUTIONS, EVEN THOSE IN PHOSPHATE, FAST** . . . 15 minutes without columns, alcohol precipitations or organic extractions.
- ☑ **ELIMINATE ENZYME-INHIBITING IMPURITIES FROM DNA SOLUTIONS FAST . . .** 15 minutes to remove protein, small RNA and other enzyme-inhibiting impurities from DNA solutions. For example, remove RNA and protein from crude mini-plasmid cleared-lysates without protease, RNase, organic extractions or alcohol preciptations. Remove enzymes such as BAP without organic extractions or alcohol precipitations.
- ☑ **ELIMINATE NEED FOR ALCOHOL PRECIPITATION OF DNA** ... 15 minute **GENECLEAN** process serves the same purpose as alcohol precipitation of DNA, often with increased recovery.
- ☑ **REMOVE TRACES OF ORGANIC SOLVENTS FAST** ... 15 minutes to remove residual enzyme-inhibiting phenol, chloroform or ether from extracted solutions of DNA.
- ☑ **"QUICKCLONE" FROM HIGH MELTING-POINT AGAROSE GELS.**

DNA TREATED WITH GENECLEAN® is free of RNA, proteins and other contaminants that inhibit enzymes and is a ready substrate for restriction enzymes, polymerases, ligases and kinases. Single and double stranded sequencing reactions are remarkably free of ghost bands caused by self-priming activity of RNA. The highly pure DNA transforms procaryotic or eucaryotic cells with high efficiency.

THE GENECLEAN® II process provides excellent recovery of single and double stranded DNA and it is not inhibited by SDS, organic solvents, protein or TBE buffers.



DNA BANDS IN AGAROSE GEL TBE or TAE
excised band 5 minutes
DNA in SOLUTION
purify DNA on GLASSMILK® 15 minutes
PURE DNA CONCENTRATED IN H₂O or LOW SALT
GENECLEAN® Kit
NEW WASH

FROM START TO FINISH ...

As the race to bring biopharmaceutical products to market quickens, companies are closely examining their allocation of resources. Many have found that, whether they are developing recombinant proteins or monoclonal antibodies, there is good reason to use CELLTECH's experience in this field to increase the quality and certainty of their development programme and final manufactured product.

CELLTECH already provides many of the world's major pharmaceutical and biotech companies with specialist development and manufacturing services. These include:

- Mammalian and microbial cell line development
- Biopharmaceutical process and assay development
- Industrial and pilot scale manufacture of clinical grade biopharmaceuticals

With licensed products already being manufactured and further product licence applications under way, CELLTECH's track record of providing quality biopharmaceutical development services is outstanding.

CELLTECH

Our **dedicated, industrial-sca manufacturing facilities,** utilizin airlift fermenters, give us a capacity more than ten kilograms of produ every year. This technology compatible with hybridomas an recombinant mammalian cell lines - both of which are routinely grown serum-free media to make therapeut grade product.

Nowhere is CELLTECH's attentic to detail more effectively demonstrate than in **product assay development an process validation support**. The activities are essential to the manufactu of a consistent product, and becom increasingly important as products reac the clinical trial stage. Our validatio procedures include the followin studies:

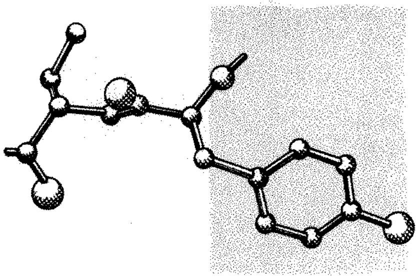
- Clearance of DNA, viruses, etc.
- Sensitivity of key process paramete
- Operation of pur fication columns
- Stability of proces intermediates

All these studie require dedicated pro duct assay develop ment and support Recent developments at CELLTEC include highly sensitive assay for murine and hamster DNA, an assays to demonstrate clearance o

cific medium and host cell derived
ntaminants.
All materials are manufactured under
GMP guidelines. Our purpose-
ilt manufacturing facilities have
cessfully passed inspection by regu-
ory bodies on both sides of the
lantic.
Comprehensive regulatory aware-
ss and support have been obtained
ough our accumu-
ed experience with
horities throughout
world. As a result,
Regulatory Affairs
m can help to ensure
cessful regulatory
missions for products manufactured
ELLTECH.
Biopharmaceutical manufacturing is
t of a comprehensive package of ser-
es which CELLTECH is able to pro-
e to achieve the therapeutic potential
our products. Additional **specialist**
vices that CELLTECH offers include:
Protein engineering — construction
of humanized antibodies
Mammalian expression — develop-
ment of highly productive CHO or
myeloma lines using a proprietary
gene amplification system
mmunopurification reagents —
development of faster, high perform-
nce protein recovery

CELLTECH has a firm financial base; it operates in the services business at a profit. This ensures that CELLTECH will remain a viable company, able to maintain its long-term commitments to biopharmaceutical customers.

As you plan the development, scale up, production, and clinical testing of your new biopharmaceutical, remember that CELLTECH is ready to meet all your needs for recombinant protein and antibody manufacture with proven technology and expertise.



To arrange a time for us to discuss your needs in complete confidence, contact Ian J. Nicholson or Susan J. Dexter at CELLTECH Limited,
Riverbend Office Park, 9
Galen Street, Watertown,
MA 02172, USA, or call
1-800-552-4934 or 617-923-4310 (Fax: 617-923-6480).

In Europe, contact
CELLTECH Limited, 216
Bath Road, Slough, SL1 4EN,
Berkshire, England, or phone UK
(0753) 34655, International +44
753 34655 (Fax: (0753) 36632).

Shows 11 injections in 90 min from a total sample of 5 μL, accomplished with P/ACE.™ Migration time CV less than .25%.

The P/ACE™ System 2000 from Beckman is designed for today *and* tomorrow. A modular system, P/ACE leads the evolution of capillary electrophoresis.

A removable detector allows multiple future detection options. Interchangeable cartridges let you change capillaries in minutes. Temperature control provides unmatched reproducibility. And sealed vials minimize sample evaporation. All unique to P/ACE. Unique too—the surprisingly affordable price.

Keep P/ACE with the latest in electrophoretic separation techniques! And achieve rapid success separating proteins, peptides, synthetic oligonucleotides, DNA fragments, and more. Call 800/742-2345, or write to Beckman Instruments, Inc., Spinco Division, Customer Service Department, 1050 Page Mill Rd., Palo Alto, CA 94304. Offices in major cities worldwide.

THESE MAGIC CUBES HOLD
THE SECRET...

... OF BETTER
FLUORESCENCE
MICROSCOPY

A secret of the Leitz fluorescence microscopy system: the cube that turns even a weak, dull specimen into a brilliant, high-contrast, high-resolution image.

The filter system offers a choice of cubes for the different applications in fluorescence microscopy.

With a unique combination of lighting system, filters, and powerful objectives, Wild Leitz optics specialists have succeeded in setting new standards in fluorescence microscopy. The best thing you can do is ask us for the documentation on your special research and diagnostic tasks.

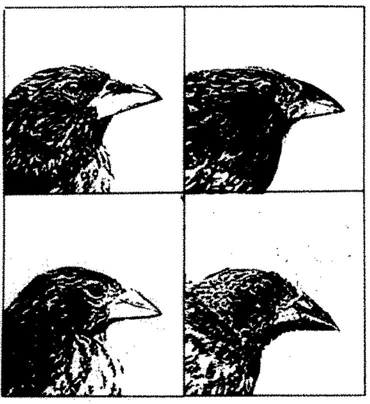
The Life of Science



EVOLUTIONARY DYNAMICS OF A NATURAL POPULATION

The Large Cactus Finch of the Galápagos

B. Rosemary Grant and Peter R. Grant

Based on their ten-year study of an isolated wild finch species, the Grants provide impressive evidence that species are capable of evolutionary change within observable periods of time.

30591-0 Pbk $24.95 £19.95 368pp
37 color illus., 75 halftones,
58 line drawings, 71 tables

FLIGHT STRATEGIES OF MIGRATING HAWKS

Paul Kerlinger

Kerlinger provides the most complete analysis to date of how hawks migrate, integrating data on the flight behavior of these raptors with information about their ecology, physiology, evolution, and nonmigratory behavior.

43157-3 Pbk $19.95 £15.95 392pp
19 halftones, 74 line drawings, 50 tables

RECENT VERTEBRATE CARCASSES AND THEIR PALEOBIOLOGICAL IMPLICATIONS

Johannes Weigelt

Translated by Judith Schaefer
Foreword by Anna K. Behrensmeyer and Catherine Badgley

This first English translation of Weigelt's 1927 classic makes available the seminal work in taphonomy. Weigelt demonstrates how an understanding of the postmortem fate of modern animals is crucial to sound inferences about fossil vertebrate assemblages and their paleoecological communities.

88157-9 Pbk $19.95 £15.95 206pp
128 halftones, 41 line drawings, 3 tables, 1 map

MAMMALS OF THE NEOTROPICS

Volume 1, The Northern Neotropics
Panama, Colombia, Venezuela, Guyana, Suriname, French Guiana

John F. Eisenberg

With plates in color and black and white by Fiona Reid and maps by Sigrid James Bonner

The first of three volumes, this comprehensive survey of terrestrial and marine mammals of the northern Neotropics includes nearly 450 species accounts complemented by discussions of biogeography, community ecology, morphology and speciation, and habitat.

19539-2 Pbk $34.95 £27.95 488pp
14 color plates, 7 halftones, 103 line drawings

MAMMALIAN REPRODUCTIVE BIOLOGY

F. H. Bronson

Bronson provides a genuinely integrated approach to the study of mammalian reproduction for students and researchers, drawing together work from laboratory physiology, animal behavior, ecology, and animal breeding.

07559-1 Pbk $17.95 £14.25 336pp
74 line drawings, 4 tables

FROZEN FAUNA OF THE MAMMOTH STEPPE

The Story of Blue Babe

R. Dale Guthrie

The frozen remains of wooly mammoths, rhinos, horses, and other Pleistocene animals are the subject of this absorbing account. Guthrie's excavation and subsequent analysis of Blue Babe, a steppe bison frozen 36,000 years ago, is the centerpiece of the book.

THE CLONING MANUAL FOR THE 1990's!

NOW AVAILABLE!

NOW AVAILABLE!

Molecular Cloning

A LABORATORY MANUAL SECOND EDITION

J. Sambrook, ***University of Texas Southwestern Medical Center***
E.F. Fritsch, ***Genetics Institute***
T. Maniatis, ***Harvard University***

Comprehensive, clearly organized, and durable for intensive laboratory use, this second edition of **Molecular Cloning** will be a resource for the experienced cloner, a starting point for the student, and a guidebook for the next generation of investigators in molecular cloning.

BOOK 1: 1. Plasmid Vectors. 2. Bacteriophage λ Vectors. 3. Cosmid Vectors. 4. Single-stranded, Filamentous Bacteriophage Vectors. 5. Enzymes Used in Molecular Cloning. 6. Gel Electrophoresis of DNA. 7. Extraction, Purification, and Analysis of Messenger RNA from Eukaryotic Cells.

BOOK 2: 8. Construction and Analysis of cDNA Libraries. 9. Analysis and Cloning of Eukaryotic Genomic DNA. 10. Preparation of Radiolabeled DNA and RNA Probes. 11. Synthetic Oligonucleotide Probes. 12. Screening Expression Libraries with Antibodies and Oligonucleotides. 13. DNA Sequencing. 14. In Vitro Amplification of DNA by the Polymerase Chain Reaction. 15. Site-directed Mutagenesis of Cloned DNA.

BOOK 3: 16. Expression of Cloned Genes in Cultured Mammalian Cells. 17. Expression of Cloned Genes in *Escherichia coli*. 18. Detection and Analysis of Proteins Expressed from Cloned Genes.

Appendixes: Appendix A: Bacterial Media, Antibiotics, and Bacterial Strains. Appendix B: Preparation of Reagents and Buffers Used in Molecular Cloning. Appendix C: Properties of Nucleic Acids. Appendix D: Codons and Amino Acids. Appendix E: Commonly Used Techniques in Molecular Cloning. Appendix F: Subcloning. Appendix G: List of Suppliers.

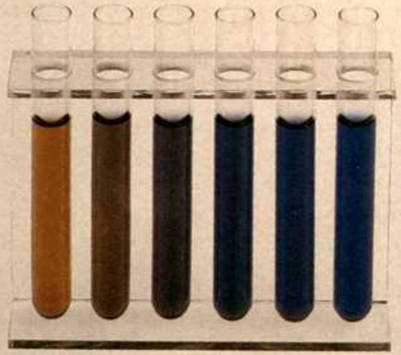
The protein assay of choice.

More researchers prefer the Bio-Rad protein concentration assay over all others, according to a recent survey. The main reasons are the sensitivity and reproducibility of this popular assay. Speed and convenience of the one-step Bio-Rad assay also rank high among users. In fact, more than 50 million Bio-Rad protein assays have been performed over the last 10 years.



The Bio-Rad protein assay has been cited thousands of times. For details on the assay, a free copy of our updated Applications Bibliography, and a copy of our Methods for Automation, contact:

Suddenly MATRIX™ Makes Filtrate LSC Old-Fashioned

New Tritium Detector Counts 96 Samples Simultaneously— Without Liquid Scintillation Cocktails and Vials

Matrix direct beta counting revolutionizes the way radiolabeled filtrate samples are counted—no cocktails, no vials, no organic waste! Just an easy-to-use microplate that holds 96 samples from your harvester, filtration manifold, or filter bottom microplate. The result? Sample preparation times are reduced from hours to minutes. Counting times cut by a factor of 50, without loss of accuracy.

Matrix performance has been proven for many applications such as MLC, Cr-release, receptor binding, RIA, tissue typing, and for many isotopes, including ^{3}H, ^{14}C, ^{35}S, ^{32}P, ^{125}I, ^{51}Cr.

Matrix cuts costs! It saves labor and eliminates the expense of LS cocktails and vials. Disposal costs are reduced to a negligible level. In fact, Matrix pays for itself in less than a year, even if you count only a few microplates per day.

Experience the Matrix difference in your lab. Call today.

BRISTOL-MYERS SQUIBB AWARD FOR DISTINGUISHED ACHIEVEMENT IN NEUROSCIENCE RESEARCH

Bristol-Myers Squibb Company presents an annual award to a scientist making an outstanding contribution in neuroscience research. Candidates for the award are to be nominated by medical schools, hospitals and neuroscience research centers. Previous award winners include Dr. Julius Axelrod, National Institute of Mental Health; Dr. Arvid Carlsson, University of Göteborg; Dr. Paul Greengard, The Rockefeller University; Dr. Tomas Hökfelt, Karolinska Institute; Dr. Walle J. H. Nauta, Massachusetts Institute of Technology; and Dr. T. P. S. Powell, University of Oxford.

AWARD: **$50,000 U.S.**

Deadline for Receipt of Nominations: **February 16, 1990**

Announcement of Award Recipient: **June, 1990**

SELECTION COMMITTEE

GEORGE K. AGHAJANIAN, M.D.	*Yale University School of Medicine and Ribicoff Research Facilities*
IRA B. BLACK, M.D.	*Cornell University Medical College–New York Hospital*
CARL W. COTMAN, PH.D.	*University of California, Irvine*
RAYMOND J. DINGLEDINE, PH.D.	*University of North Carolina at Chapel Hill*
FRED H. GAGE, PH.D.	*University of California, San Diego*
SOLOMON H. SNYDER, M.D.	*The Johns Hopkins University School of Medicine*

Rules and official nomination forms are available from: Secretary, Award Committee

Opportunity for Europe's science

One of the best, but smallest, of Europe's research organizations wants to be bigger. Not before time. But will those who hold the purse-strings agree?

NEXT week's General Assembly of the European Science Foundation (ESF) at Strasbourg could be crucial for the future of basic science in Europe. ESF's members, more than 50 research councils from 19 countries (with Iceland joining next week), will there have to take a view of the scale on which ESF functions. Huge sums are not at stake. The annual budget of ESF now is less than FF14 million, or less than $2 million. For the time being, the expansionists' plans would merely increase the scale of operations threefold. The choice is between the present shoestring and one only a little thicker. But there are two reasons why the issue is more important than that. First, ESF's budget is highly geared: each franc spent may be matched by 10 francs spent by member organizations. Second, the new activities on which ESF wishes to embark would give it, for the first time, an executive (if still small) role in the conduct of European collaboration in science. It thoroughly deserves one.

Here is why. ESF is catholic in the best sense. It follows the European mainland's broad understanding of what science is. The humanities and social sciences stand alongside nuclear physics and the exploration of interplanetary space. But ESF is deliberately not restricted geographically to the European Economic Community (EEC), but covers Scandinavia, Switzerland and Austria and even Turkey. People from Eastern Europe (and even China) have taken part as individuals in particular programmes. ESF now claims, rightly, that a nongovernmental organization such as itself is well placed to bring about more durable collaboration. Indeed, ESF seems to have been talking informally to two East European countries, but says that no "single dramatic initiative" is in prospect. ESF is certainly better placed to make a research bridge with the East then any other European institution. Will the tumultuous events of the past few weeks persuade next week's assembly to throw caution to the winds?

Success

As a club for European research councils, ESF has 16 successful years to boast about. It is organized to identify potentially fruitful fields for research collaboration, which are then carried through by groups of individual researchers supported, when necessary, by the research council members. The European Geotraverse Project, a coordinated programme (now almost finished) of deep seismic soundings from north to south in Europe (with a projection into North Africa) is a good illustration. ESF launched the project in 1983 at the urging of interested geophysicists, since when research councils electing to participate have paid for the direct costs of coordination (more than FF1 million this year) and have spent much more on research grants to support the actual work. The general opinion is that the implications of the data gathered will be more valuable than would have been the sum of the several uncoordinated parts. Much the same can be expected of the programme, likely to be approved next week, on the genetics of psychiatric illness, recent disappointments notwithstanding (see page 222). The plan is to harness resources on a European scale in the search for families likely to be useful in the search for genes implicated in psychiatric illness.

ESRS

But ESF has other feathers in its cap, most conspicuously the European Synchrotron Radiation Source now being built at Grenoble. The case for that was first made by an ESF committee. The funds were prised out of reluctant governments (chiefly West Germany and France) by ESF diplomacy. It is absurd that so little credit should have stuck to ESF for its midwife's role. This project in particular would have been carried through in half the time (seven rather than 15 years) if ESF had had more executive responsibility. ESF now says it wishes to play a more direct part in projects such as these. It could do worse than cut these new sharper teeth in the European VLBI Consortium's plan for the more effective coordination of data gathered by Europe's radiotelescope, still orphaned for lack of funds (see *Nature* **337**, 301; 1989).

What else is there to do? In the past few years, ESF has encouraged several successful informal networks of laboratories and individuals in fields as different as polar science and the use of longitudinal studies in childhood development. Again the principle is that ESF uses its own money to tell whether proposed networks will meet a need, often by organizing a sample workshop or two, whereupon administrative and operating costs are met by the participants. Now ESF wishes to go further — first by using its own money to organize research conferences and then by administering a scheme for up to 500 three-year postdoctoral fellowships a year. In a sharp break with previous practice, ESF would like to spend its own funds on these ventures, which means a bigger budget. Explicitly, ESF is saying that it has won the right to be regarded as the natural executive agent of its members for transnational collaboration on a European scale.

The argument is sound, but will it be heeded? Two issues are bound to dominate next week's debate: how promising are the new schemes, and can they be afforded? The underlying objectives are similar — to find ways of giving Europe's scattered academic communities a sense of being part of a critical mass. ESF hopes to be given funds next week to run a two-year pilot programme of conferences, but the case for the potentially more expensive postdoctoral programme is even stronger, if only because there is at present no general means by which people embarking on careers as independent researchers can be helped to move from one European academic centre to another. The underlying objective is to create within some European geographical context a sense that the academic community is a well-integrated whole, untrammelled by national or state boundaries. Until that happens, European science will not make the best of its potential and will remain at a disadvantage with North America.

But there are also difficulties. In breaking this new ground, ESF will, for example, for the first time encounter the too-familiar corrosive internal arguments about 'fair shares' that plague most international organizations: why should members from one country contribute when the immediate beneficiaries may be from elsewhere? The complaint mistakes the objectives, which are communal, not sectional. Specifically, postdoctoral fellows from one country who serve their time in a second and then become full-time academics in a third are only a 'loss' to the first two if the European academic community remains as balkanized as it is at present, which amounts to saying that neither ESF's plans nor other initiatives in the air will have much effect. That is a counsel of despair.

There are also practical difficulties; most postdoctoral fellowships are linked with research grants, for example, especially in the natural sciences. A postdoctoral fellow cannot work effectively without research funds, but universities are at present able to provide for only a few out of their own resources. But it would defeat the purpose of the new schemes if they were confined to fields in which research is relatively cheap, as in the social sciences. Uncertainties such as these, rather than the sheer cost of the postdoctoral scheme (which nevertheless could easily exceed the equivalent of $30 million a year) will determine what happens next week. It is to be hoped that ESF's assembly will be ready at least to experiment.

What matters most of all is that ESF's members should have a clear idea of why they are in business at Strasbourg. ESF is by no means the only European institution for the encouragement of transnational science, but it is a distinctive one. It differs from the organs of the European Economic Community (EEC), for example, geographically and by its concern for basic rather than applied science. (The EEC should pay more attention to basic science, but that is another matter.) ESF is also concerned with quality in research, not merely with getting things done. However much it grows, it will not in the foreseeable future be a big spender, but its record shows that its influence can far exceed the scale on which money runs through its hands. The opportunity, now, is to recreate the circumstances of the eighteenth century, when European scholarship was free and also European in the broadest sense — manageably so because it was so much smaller. The prize, the reinvigoration of European scholarship — could also be disproportionately handsome. □

Strength via adversity?

Having outlasted an administrative attack, the US fusion programme must not subside into somnolence.

THE only thing worse than a federal science administrator who knows nothing about science is one who does. That, apparently, is the lesson that physicists in the US magnetic fusion programme will be obliged to draw from the recent departure of Robert Hunter from the Department of Energy, where he had been director of energy research. In Congress and elsewhere, those who have been trying for decades to persuade tokamaks to burn deuterium and tritium had been complaining about Hunter's activities: he diverted funds from magnetic to laser fusion research, tried to stall construction of the Compact Ignition Tokamak and, worst of all, refused to take physicists at their word when they assured him the magnetic fusion programme was proceeding as planned towards commercial energy generation.

Hunter was, no doubt, politically a clumsy man. He shifted money from one budget category to another without consulting the appropriate Congressional committees. He further irked Robert Roe, the chairman of the House Committee on Science, Science and Technology, by observing in a departmental memorandum that Princeton was not the automatic choice for the site of a new tokamak because of political concerns over radioactivity; Roe, coming across this note at a fractious hearing, was in no mood to be told by a federal administrator what was or was not a political issue in his home state.

There will be many sighs of relief and little lamentation at Hunter's going. But before the tokamak community congratulates itself too much, they should ponder something: for the first time since the oil crisis of the early seventies, fusion energy was the subject of a noisy political debate. A dozen congressmen grappled intently with plasma quality factors and confinement times. In fighting off Hunter's attack, scientists who had languished under level funding for fifteen years found themselves being praised by some influential voices. With a more timid and less engaging character in Hunter's place, the magnetic fusion programme may well return to the political backwaters. Physicists had better make sure that this does not also mean a return to the financial neglect and sloth of the last decade. □

Nuclear installations not the cause of cancer?

- Risks similar at rejected and chosen sites
- Unidentified risk factor may be involved

Washington

RESEARCH published in Britain last week shows that the mortality rate from leukaemia and Hodgkin's disease in young people is higher not only near existing UK nuclear power stations but also near places being considered as future power station sites. This further tips the balance of the evidence away from the theory that radioactive discharges are behind the increases.

Epidemiological research in Britain, the world leader in studies of the health effects of nuclear installations, has so far been inconclusive in attempts to prove or disprove a link between radioactive discharges and an increase in the incidence of leukaemia and Hodgkin's disease in young people living nearby.

After examining the evidence last year, the Committee on Medical Aspects of Radiation in the Environment, an independent commission, concluded that some unidentified feature of Britain's nuclear reprocessing plants at Sellafield in Cumbria and Dounreay in Scotland was the most likely cause of the increased incidence of leukaemia, but could not attribute the increase to radioactivity in the area because the measured levels were so low.

Leo Kinlen of the Cancer Research Campaign's epidemiology unit at the University of Edinburgh later found evidence to support the theory that the increased leukaemia incidences might result from viral infections. His theory proposes that a rapid influx of population in the vicinity of a nuclear installation, usually located in an isolated area, brings an infection to which the indigenous population has not evolved resistance.

In an attempt to decide whether the increased cancers are caused by radiation from nuclear installations or by some other contingent feature, Paula Cook-Mozaffari, Sarah Darby and Richard Doll of the Imperial Cancer Research Fund Laboratories in Oxford compared mortality data from areas near two Central Electricity Generation Board (CEGB) nuclear power stations and six other sites being considered by the CEGB for the construction of power stations. They reported in *The Lancet* last week that the increased risk of mortality due to leukaemia and Hodgkin's disease in young people was "strikingly similar" in both groups.

Although they declined to suggest any reason for the increased mortality, they suggested that these areas might share "important unrecognised risk factors" other than environmental radiation pollution. But they also point out that there had been no sudden population influx in the potential sites, which argued against the viral infection theory.

Evidence is now mounting, says Darby, against the theory that radioactive discharges are responsible for the increased cancer risk, although at Sellafield, home to one of Britain's two nuclear reprocessing plants, the discharges and the increased cancer risk are much higher and the issue is still open. At Dounreay in Scotland, the site of Britain's other reprocessing plant, the reported increased leukaemia incidence is also significantly higher than in the areas in this study.

Kinlen says the new results are consistent with the theory that in isolated coastal areas, which would be suitable sites for nuclear installations, the pattern of human interaction is different from that in the average large inland town and could explain the increased risk for certain types of cancer. He adds that "it is possible, if not probable" that the new results are recording the same effect he saw on a smaller scale and predicts that a similar result would be found in any rural coastal area, regardless of whether it was a potential site for a nuclear power station.

Christine McGourty

Cancer near potential sites of nuclear installations, by P. Cook-Mozaffari, S. Darby & R. Doll, *Lancet* **II**, 1145–1147 (1989).

NUCLEAR POWER

Privatization spells end of a nuclear dream

Washington

THE future of the nuclear industry in Britain is in doubt after last week's announcement by the government that it was abandoning plans to build three new PWRs (pressurized water reactors). The reversal of the plans to expand the nuclear industry is an about-face by the Conservative government under Prime Minister Margaret Thatcher, a staunch advocate of nuclear power, but was inevitable given the government's determination to privatize the electricity industry and the refusal of the soon-to-be-privatized local electricity boards to carry through the £7,000 million PWR programme and face the huge costs of nuclear waste disposal and of de-commissioning old power stations.

Strong opposition to nuclear power forced a long and controversial public inquiry into the safety and design of Britain's first PWR at Sizewell in Suffolk. The plans were approved 18 months ago and construction is under way. The subsequent inquiry into a second PWR, at Hinkley Point C in Somerset, has been running for more than six months and was was drawing to a close, but will now be abandoned along with plans for another two PWRs at Sizewell C, and Wylfa B in Wales.

Opponents of nuclear power scored a major victory during this inquiry when the Central Electricity Generating Board, which has always promoted the low costs of nuclear power, was forced to disclose figures showing that its coal-fired power stations are cheaper.

In an attempt to ensure that nuclear power was not neglected after privatization, the government had stipulated that by the year 2000, 20 per cent of the electricity demand must be met by non-fossil fuel sources to maintain fuel diversity. A new private company, National Power, was to be responsible for nuclear power generation. But its chairman-designate, Lord Marshall, is confidently expected to resign; and now the 10 existing Magnox reactors and 7 AGRs (advanced gas-cooled reactors) will be retained in a new publicly owned company.

Former director of the UK Atomic Energy Authority, Lord Marshall may not be the man to run a coal-fired CEGB.

Christine McGourty

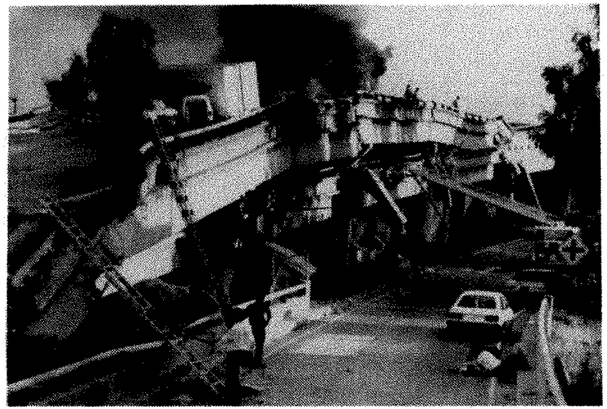
LOMA PRIETA EARTHQUAKE

Testing time for Caltrans

San Francisco

A SIMULATED earthquake on a portion of intact freeway and an elaborate computer model of the San Francisco Bay Bridge are among the studies likely to be adopted by California officials in an effort to understand what happened during the 17 October Loma Prieta earthquake. At a meeting scheduled for late last week between representatives from Caltrans, the state transportation department, and University of California engineers, several proposals for roadway studies were due to be debated, but Caltrans spokesman Jim Drag confirmed that the simulated quake and the Bay Bridge studies seemed likely to be approved.

Also last week, California governor George Deukmejian signed 24 earthquake relief measures, including a sales tax increase of a quarter-cent per dollar, and officials announced that the Bay Bridge would reopen on 17 November, exactly one month after the quake.



Looking south on Interstate 880 on the Tuesday evening. (AP).

The highway test involves an intact section of Interstate 880 in Oakland, just south of the Cypress Viaduct section which collapsed during the upheaval. Apart from a firmer foundation, the section is almost identical to the portion that collapsed. The prevailing theory is that the upper deck failed because the supporting columns and the joints that bind them with the lower deck had not been adequately reinforced. Two tests will examine these and other ideas.

In one, hydraulic jacks mounted on steel frames under both sides of the roadway will be used to simulate the sideways movement of the 7.1-magnitude quake. An array of electronic instruments and cameras will measure the displacement and strain developed at specific points, and record the physical damage.

The overpass will first be tested in its present condition, after which engineers will reinforce the columns with steel beams, and then slowly bring the freeway to the failing point, which might take as much as three million pounds of force. The objective, says Jack Moehle, a structural engineer at the University of California at Berkeley, is to test proposed strengthening techniques for other San Francisco Bay Area double-decker freeways. Three similar roadways in San Francisco that were damaged in the earthquake are still closed.

In the second test, which will alternate with the hydraulic-jack experiment, a pair of vibration generators will be attached to the same freeway section. Attached to the upper deck, the twin 'shakers' rotate heavy weights in opposite directions at a synchronized frequency, so that the centrifugal force is focused in a specific direction along the roadway. The force, of the order of 10,000 pounds, will not be great, but by repeated application at a steady rate it will test the structure's endurance against vibration.

Accelerators attached to the freeway will allow engineers, knowing the mass of the deck, to measure the forces developed in the supporting columns. "If we know the total force in the structure and how it displaces under that force, we can develop a good computer model of the resisting mechanism", says Moehle.

The tests will be finished by Christmas, when the entire freeway span will be demolished. Because the tested section will not be "failed" in its original condition, engineers will have no direct measure of how the Cypress section really collapsed, but the investigators hope that demolition crews will haul a few columns away for further study in the laboratory.

The Bay Bridge study will be confined mainly to laboratory simulations and computer modelling. Faculty and students from the structural engineering programme of UC Berkeley's civil engineering department have alredy been amassing damage information, from notebooks, photographs, videotapes and sketches. They plan to supplement this data with other input to develop a detailed computer model of the bridge that extends even to its underlying soil.

"Our main goal is to make sure our computer programs — simulations, modeling, all the tools that we have to do the analysis — are capable of predicting events like this and damage like this", said Abolhassan Astaneh, a UC Berkeley assistant professor of civil engineering. These studies, he hoped, will enable engineers to recommend specific retrofitting plans and other modifications, so that the bridge can withstand "the big one".

Robert Buderi

COMPUTER SOFTWARE

Federal policy makes trouble

Washington

MANY examples of "waste, fraud and abuse" in the federal government can be attributed to problems in developing software, according to a report released last week by the US House of Representatives Committee on Science, Space and Technology. On everything from budgeting to intellectual property rights, it says, government policies "have congealed over time in a manner almost perfectly designed to thwart the development of high-quality software".

Although no single action will instantly solve the government's software woes, the committee staff recommends that a working group on improving software development be set up in the president's Office of Science and Technology Policy with the aim of making long-term changes in the government procurement system.

At present, government contracts specify in "excruciating" detail exactly how a system will look at delivery several years in the future, so when the inevitable changes are introduced, software quality is adversely affected and development costs increase.

Reducing overall costs would require spending more time and money in the design stage, when it is much cheaper to correct an error, than in the maintenance phase. But this strategy is discouraged by the process for obtaining congressional approval, which requires initial costs to be minimized.

The report, stemming from an investigation into faulty software in a radiation therapy machine which caused several deaths, also calls on the National Institute of Standards and Technology to play a greater role in improving software evaluation. At present there is no infallible method for assessing quantitatively the safety of software used in, for example, aircraft flight controls or nuclear reactors, in which software flaws can put lives at risk. The federal government's "software woes" are exacerbated by the staff crisis created by its inability to compete with the private sector in attracting software specialists.

Computer security and ethics also came under scrutiny last week in the House subcommittee of criminal justice, which is considering two bills to increase the penalties for damaging hardware and software as a deterrent to hackers. But researchers and legal experts are divided over the need for new legislation, definitions of "authorized access" and how to increase computer security without restricting free exchange of information. Action on the bills is being delayed pending the outcome of the trial of Robert Morris, the Cornell University graduate student whose 'virus' disabled thousands of computers last year.

Christine McGourty

COLD FUSION

Official thumbs down

Washington

To no one's surprise, the panel set up by the Department of Energy (DoE) to assess cold fusion has sent in a negative report. An interim opinion released earlier this year by the panel, a group of 23 electrochemists, nuclear physicists and materials scientists assembled by the DoE's Energy Research Advisory Board (ERAB), acknowledged that there were some odd and unexplained results in the air but recommended against any special support of cold fusion experiments (see *Nature* **340**, 174; 1989). The panel's final report expresses the same verdict a little more forcefully, but the ERAB meeting at which the report was approved and passed on to DoE Secretary James Watkins did reveal some differences of opinion on the significance and credibility of the handful of 'positive' results still extant.

Summarizing the final report, John Huizenga, a professor of physics and chemistry at the University of Rochester and one of the ERAB panel's co-chairmen, showed little patience with those who have continued to claim that there is at least a little evidence for cold fusion of the heat-producing variety. None of the calorimetry, he declared, was of good enough quality to be believed, and in any case calorimetry alone would never prove the case. Huizenga was particularly unhappy with those who argued that because the claimed excess heat could not possibly be of conventional origin it had to be nuclear, despite measurements which showed unequivocally that no fusion products were being generated.

Discounting the calorimetry, the only anomalous claim still needing an explanation was that of Kevin Wolf of Texas A&M University, who repeatedly finds tritium in his electrochemical cells. But new evidence from Wolf, discussed at last week's ERAB meeting, argues against a nuclear origin. Tritium produced by deuterium fusion comes with an energy of 1 MeV and is accompanied by a 3 MeV proton. Energetic tritons will react with deuterium, either in the palladium electrode or in the electrolyte, producing secondary neutrons, and the protons can excite some palladium nuclei, which give up a 500 keV photon on de-excitation. In his latest experiments, Wolf has searched for both these secondary signatures and found nothing. His tritium, therefore, must have some kind of low-energy origin.

Nevertheless, Wolf has also searched minutely for sources of contamination, and found nothing there either.

This puzzling result, together with a few calorimetric measurements that he found somewhat convincing, led recent Nobel prizewinner Norman Ramsey of Harvard University (see *Nature* **341**, 556; 1989), the panel's other co-chairman, to conclude that the case against cold fusion was not closed. At his insistence, a preamble was added to the report's conclusions which notes that "it is not possible to state categorically that all the claims for cold fusion have been convincingly either proved or disproved".

Huizenga felt that this preamble "weakened" the report, but Ramsey and some others felt that the report would undermine itself if it looked too dogmatic in its dismissal of the evidence.

On the subject of the low-level fusion process espoused by Steven Jones of Brigham Young University, the panel agreed that more work was needed, although here again Huizenga, noting that all the claims were of marginal statistical significance, seemed less impressed than some of the other panel members that there really was a phenomenon to be explained.

Although he showed some sympathy for those still making claims for cold fusion, Ramsey also said that if the results on which the claims were based came from his laboratory, he would keep quiet and do more experiments until he understood better what was going on. The ERAB report accepts that people are free to submit experimental proposals to granting agencies in the hope of obtaining support for cold fusion experiments, but recommends that only if experiments are likely to yield useful results — closed-cell calorimetry with simultaneous nuclear monitoring is deemed essential — should support be given. **David Lindley**

EAST GERMAN EXODUS

Problems remain for those who stay

Munich

EAST German researchers now living in West Germany are happy but sceptical about the events in East Germany that culminated in last week's opening of the Berlin Wall. No one disputes that the opening of the borders is a momentous and irreversible step, but many doubt that the effects of 40 years of Communist repression can be wiped away overnight: the repressive system is more deeply entrenched in East Germany than, for example, in Hungary, which has also enacted radical reforms this year.

Under the old system, said a number of researchers, Party members and other desirables were given the opportunity to travel abroad, publish in foreign journals and make progress in their scientific careers, but those who lacked an ideological pedigree were cut off from the West and forced to engage in political activities against their will. The pessimism brought on by such obstructions caused these people, like so many others, to escape.

Those who tried to leave by legal means found that as soon as they submitted visa applications, they were forbidden to work in their laboratories. One said he was reinstated only after an invitation to a scientific meeting from a prominent West German research institution, in which he now has a job. But the only way to find out about such opportunities is to have personal and professional contacts, said another.

Researchers said after the recent lifting of travel restrictions that they were waiting to see if the changes are large enough to encourage development of a system based on personal achievement and not privilege. Even so, East German research laboratories will still lack the money to order basic supplies, let alone to subscribe to foreign journals. Steven Dickman

West Germany continued to welcome all those who came over from East Germany on Friday, even though the capacity of the refugee camps had nearly been exhausted. Most of the refugees who had arrived before the Wall came down seemed to be in practical, not academic, professions, although an accurate tally was made impossible by the large numbers. But organizations involved in helping East German researchers and academics get on their feet in West Germany said they would need much more money to continue the process.

Uta Paffhausen of the Education Ministry reported that the number of applications for "adjustment aid", given to help East German emigrants find academic posts, had risen to about 50 in the past two months. The grants are provided by the ministry as well as by the Otto Benecke Foundation. The ministry also administers a programme to provide fellowships for refugees whose training is unsuitable for working in West Germany. The two programmes were to provide a total of DM 24 million ($13 million) in 1990 when the refugee total was still expected to be about 60,000. But by 10 November, the number had topped 500,000, including 200,000 East Germans and another 300,000 ethnic Germans from Poland and the Soviet Union. Photo: The wall near Checkpoint Charlie last Friday, seen from the East (AP).

GLOBAL CHANGE

Politicians still only talking

Boston

In a week marked by vocal debate over global climate change, a group of representatives from private foundations gathered quietly with scientists and international security experts in Cambridge, Massachusetts, last week to explore the international political fallout from anticipated changes in the environment.

While British Prime Minister Margaret Thatcher called upon the UN General Assembly to lead the way in worldwide action, and environmental policy-makers from 68 nations gathered in the Netherlands failed to agree on international limits on carbon-dioxide emissions, those meeting in Cambridge tackled social and legal issues such as the prospect that drastic climate change could produce 'environmental refugees' and the idea that environmental concerns could become so crucial that countries would be justified in overriding the sovereignty of others to enforce protective measures.

At the Cambridge meeting, which was sponsored by the American Academy of Arts and Sciences, the presence of representatives of some of the largest private US foundations signalled a mounting interest in global change research. Although no new financial commitments were announced at the meeting, several foundations, including the John D. and Catherine T. MacArthur Foundation and the Social Science Research Council, have already earmarked funds specifically for research on global environmental change.

But dissent over political choices overshadowed scientific uncertainty. The scientists present agreed that precise and consistent models of global climate change are decades away, but nonetheless presented a fairly uniform and troubling consensus about the threats posed by ozone depletion and trapped greenhouse gases. It was the social scientists and security experts who clashed most severely in their assessment of the political implications of the issue.

Some, like George Rathjens, professor at the Center for International Studies at the Massachusetts Institute of Technology, argued that the economic costs involved in curbing emissions may be too high to allow immediate action, and that the costs "diminish the prospects for international agreements". But others declared that "we know enough now" to justify a push for international cooperative measures — even coercive measures.

Speaking unofficially on behalf of the Brazilian government, Eunice Durham, an anthropologist at the University of São Paulo, bristled at even the notion of international coercion or pressure to reduce global warming. In the view of the Brazilian government, said Durham, "military action [would be] justified" if the nation's sovereignty over the Amazon rain forest is in any way challenged. Furthermore, she added, deforestation "is not going to be stopped unless there is a viable alternative development plan for the region". Similar divisions and disagreements emerged at the international conference in the Netherlands. Despite President George Bush's claims of the need for a "war against global warming", the United States, together with Japan and the Soviet Union, led the way in thwarting the endorsement of a specific timetable for curbs on emissions of carbon dioxide. Most of the 68 countries present at the Netherlands environmental conference wanted to freeze allowable emissions of carbon dioxide by the year 2000.

William K. Reilly, head of the US Environmental Protection Agency, stressed the fact that the United States agreed in principle to the need for international emission levels. But many critics in the United States and elsewhere were disappointed at the outcome of the Netherlands meeting, and criticized the United States for its deliberate inaction. As one critic put it, the US position made Bush's strong statements about global warming look like "a lot of hot air". **Seth Shulman**

GLOBAL KNOWLEDGE

Americans and Russians mostly at sea

Washington

When George Bush and Mikhail Gorbachev meet upon the Mediterranean Sea next month, they will be on equal terms in at least one respect: their respective countrymen will have an equally vague idea of where in the world they are. Asked to identify 16 locations on the map below, US citizens got an average of 8.6 correct, and Soviets did a little worse, scoring 7.4. Swedes and West Germans did best (11.6 and 11.2 correct identifications); the Japanese averaged 9.7 and the British 8.5.

The results of the survey, conducted by the Gallup organization for the National Geographic Society specifically to compare knowledge of geography in ten countries, have been taken in the United States as more evidence that the educational system, no matter how many brilliant scholars it may produce, is failing the general population. For Americans, the most alarming result of the country-identification quiz was that the youngest age-group (18–24) did significantly worse than the rest of the population: for the other countries, younger people tended to do as well as or better than their elders. Last year, an international survey put US high school students near the bottom of the class in science (see *Nature* 332, 195; 1988).

But the Soviets, if the responses of 1,500 inhabitants of Moscow and Kursk reflect the knowledge of the population as a whole, have even more reason for alarm. Although 88 per cent of the Soviet sample had taken a geography course in school, and 61 per cent thought geographical knowledge a necessity, their achievements belied these ideals. Only 38 per cent of the Soviets knew where Afghanistan was.

AGENT ORANGE

'Not guilty' verdict challenged

Sydney

FOUR years after a Royal Commission adjudged that the widely used defoliant Agent Orange had caused no measurable or lasting ill-effects in soldiers in Vietnam, a group of Australian scientists has called the commission's findings unscientific. Eighteen biologists, chemists and immunologists from some of Australia's leading universities held a conference in Canberra last April under the title *Evatt Revisited,* in reference to the 1983 Royal Commission on the Use and Effects of Chemical Agents on Australian Personnel in Vietnam, headed by Justice Phillip Evatt. The proceedings of the conference were published last week, and include the charge that the commissioners simply duplicated large sections of the submission by Monsanto, the US chemical company that makes Agent Orange.

The Evatt Royal Commission was set up to determine whether Australian servicemen who served in Vietnam were more likely than others to suffer from cancer and whether their children had a higher probability of birth deformities. Since the commission released its findings in July 1985, it has been the target of complaints from the Vietnam Veterans Association of Australia (VVAA), from witnesses who testified before it and now from some of Australia's most senior scientists. Critics say, among other things, that the report is shallow and extravagantly worded, that scientific evidence was poorly interpreted and that VVAA witnesses were treated as "hostile".

In 1987, the federal government ordered an inquiry into the findings of the Royal Commission, and concluded that the commission should not have come out with its "not guilty" assertion. The report maintained that the commission's findings and conclusions were sustainable but that it lacked credibility because of the manner in which the inquiry was conducted. But the new criticisms raised in *Evatt Revisited* are the first to complain about the commission's handling of the scientific evidence.

Ted Steele, a biologist from the University of Wollongong and one of the editors of *Evatt Revisited,* says that the commission's conclusions that exposure of civilians to Agent Orange had little or no effect on birth abnormalities was not warranted. He says that new evidence of birth abnormalities has come forward since the Royal Commission did its work, and believes that such findings "suggest that more cautious recommendations should have been forthcoming both from the Royal Commission and their scientific advisors". But Steele also has a more serious charge: he says that "large tracts of the report were plagiarized verbatim from the submission of Monsanto". But John Coombs QC, counsel assisting the commission, says Steele's allegation is "nonsense". He points out that it is common practice for a commission to incorporate appropriate parts of the submissions received into its report, and adds that "part of the VVAA submission was also reproduced".

TOXIC WASTE DISPOSAL

Commercial plans delayed

Cape Town

PLANS by a Cape Town company, Peacock Bay Environment Services, to build a toxic-waste disposal plant that would process imported as well as domestic waste have been put on hold by Gert Kotze, South Africa's minister of the environment. Kotze announced last month that the government would not consider licensing the importation of toxic waste before it had been presented with the results of a newly commissioned survey on domestic waste disposal. The survey will be conducted by the CSIR's Foundation for Research Development.

According to Sidney Sanders, a director of the company, the importation of foreign waste is essential for the economic success of the proposed R400 million ($160 million) development.

He also claims that the plant offers "the first viable alternative to the inadequate way in which toxins are being disposed of in this country". But unease over the plans derives more from worries over the transportation of waste than its treatment at the plant. A local toxic-waste transport company has indicated its reluctance to transport more waste by road, because the risk of accidents is too high, but Peacock Bay proposes to use the rail system instead.

The development, whose intended site is Alexander Bay, on the west coast 600 km north of Cape Town, is believed to be the first proposed under the new Environmental Conservation Act, promulgated by parliament in June of this year. The Act makes environmental impact assessment a legal prerequisite, and the Peacock Bay company says it has followed the procedures laid down by the act "to the letter", and has spent R750,000 ($300,000) on an impact assessment study.

But local environment groups, spearheaded by the newly formed pressure group Earthlife Africa, have come out against the idea of importing toxic waste. Kotze, meanwhile, has accused Earthlife Africa of sowing suspicion about the government's integrity, but his department nonetheless appears to be sensitive to public reaction.

Michael Cherry

US SECURITY

FBI interference with libraries criticized

Washington

FRESH concerns arose last week over interference by the Federal Bureau of Investigation (FBI) in the operation of academic and other public libraries. A year ago, the FBI came under attack for its long-standing Library Awareness Program (LAP), in which it tried to enlist the help of librarians in identifying foreign spies who might be seeking access to scientific and technical libraries (see *Nature* 336, 507; 1988). Now documents obtained by the National Security Archive (NSA), a non-profit Washington library and research centre, reveal that librarians who refused to help the FBI or publicly criticized LAP were subsequently investigated to see if the campaign against LAP was itself part of a Soviet plot.

The NSA, whose collection includes a variety of unclassified and declassified government materials, requested documents concerning LAP under the Freedom of Information Act, and then filed a follow-up lawsuit when the FBI failed to deliver. Under an agreement reached earlier this year, the FBI has now released 1,200 pages of internal documentation, blacked out in some places.

The FBI memoranda reveal that activities under LAP were continued through the past two years despite assurances from senior officials to the American Library Association (ALA) that the programme was put in abeyance after December 1987. FBI agents were, however, told not to refer to LAP by name because of the adverse publicity. And one internal FBI communication, dated 6 February 1989, notes that although 266 individuals had been subjected to "indices checks" since November 1987, only eight "references" were found. The purpose of these background checks, according to the FBI memo, was to "determine if a Soviet active measures campaign had been initiated to discredit the Library Awareness Program". The nature of the eight "references" turned up is not revealed.

But according to an FBI spokesman the ALA and the NSA are reading sinister motives into routine matters. Whenever anyone writes to the FBI on any subject, files are checked to see if the person has had any previous contact with the FBI, has been investigated by the bureau, has a criminal record, and so on. The "indices checks" referred to in the memo are simply searches through existing FBI files to see if a positive entry exists in any one of about 250 categories. The spokesman emphasized that these checks do not involve sending out agents to conduct personal investigations or questioning. Nevertheless, lawyers for the ALA are sifting through the 1,200 pages of FBI documents to see if there are any grounds for further action.

David Lindley

GENETIC ENGINEERING

New law is overdue

Munich

A West German court last week ordered Hoechst AG to cease construction of a nearly completed plant that would use genetically engineered bacteria to make human insulin. The court ruled that it could not approve the licence granted for the construction of the plant because there is no legal basis for regulating the use of genetic engineering. The decision increases the already intense pressure on the government to pass a law regulating genetic engineering in factories and laboratories.

The court rejected the relevance of the West German Federal Emission Protection Act, which had been used as a legal basis for constructing at least one other facility using genetic engineering. The decision reversed earlier rulings by lower courts which had upheld Hoechst's right to build the plant despite legal challenges from local residents. Hoechst may appeal to the federal constitutional court at Karlsruhe for a reversal of the decision on constitutional grounds, but has not yet decided if it will do so.

The Hoechst plant would use the bacteria *Escherichia coli* to produce human insulin, as US companies have been doing for a decade. Hoechst has invested an estimated $60 million in the plant and a spokeswoman said that the company intends to "fight further" for the use of genetic engineering in drug manufacture in West Germany. She called it "astounding" that there could be so much fuss over a technique that uses *E. coli*, which is found in the human intestine.

But the debate over genetic engineering here has been marked by the almost religious belief held by opponents that all genetic engineering is hazardous. Although declining to rule on ethical or safety aspects, the court seemed to agree, saying that genetic engineering represented a "new dimension and quality" of technology with "risks for human beings and the environment that could not be properly assessed at this time . . . . Only the democratically elected legislature" can decide how genetic engineering could be regulated.

The court's decision adds urgency to efforts to speed passage of a 'basic law' for genetic engineering that has been under discussion all year (see *Nature* **340**, 85; 1989). The cabinet published its views on the latest version of the law on 9 November, the day after the court decision, preparing the way for discussion in the Bundestag this week.

It made some concessions to the *Länder* (states), for example agreeing to more public participation in the licensing procedure, but rejected the request of the *Länder* that they be allowed to carry out the provisions of the new law. The cabinet warned that this could potentially lead to a variety of interpretations of the law, which would be bad both for industry and for basic research.

But before the law can be put into practice, detailed regulations must be drawn up by the Health Ministry and the regulations attached to the law are "as important as the law itself" for basic research, said Ernst-Ludwig Winnacker, vice-president of the Deutsche Forschungsgemeinschaft (DFG). The effect on basic research "will depend on the wording", he said, and DFG, which is the main source of outside funding for basic research at universities, has volunteered to help draw them up.

Steven Dickman

ANTI-CLOTTING DRUGS

Approval for TPA competitor

Washington

The approval of SmithKline Beecham's blood-clot-dissolving drug Eminase by the blood and blood products committee of the Food and Drug Administration (FDA) on 31 October puts the drug just one step away from being released for sale on the US market. Eminase, a complex of the already available thrombolytic drug streptokinase with human plasminogen, had been expected to win approval several months ago, but was held up for additional scrutiny by an FDA advisory committee amid reports of pressure from Genentech, which manufactures the rival drug Activase (tissue plasminogen activator, TPA).

David Stump, Genentech's director of clinical research, reported to the advisory committee that he had evidence of antibody production in response to the plasminogen portion of Eminase.

But the results presented by SmithKline Beecham indicated no evidence of increased autoimmunity. Alan Wachter, manager of scientific information at SmithKline Beecham, emphasized that the approval of Eminase was unanimous. Although no price has yet been set, the company says the drug will be cheaper than existing thrombolytic drugs. Eminase has a longer half-life in the bloodstream than streptokinase, and can therefore be administered in 2–5 minutes instead of being infused over an hour. Activase has to be given over a period of three hours.

A large mortality study comparing the efficacy of Eminase, streptokinase and Duteplase (Boroughs Wellcome's TPA) is in progress and results are expected within the next few years. **Diane Gershon**

IN VITRO FERTILIZATION

Political pressure means poor research

Washington

In a report issued last week, the Institute of Medicine (IOM) *called on the NIH to* coordinate vigorous research programmes in basic reproductive biology and in the technologies of medically assisted conception in order to improve the practice of *in vitro* fertilization (IVF) and embryo transfer in the United States. Neglect of research in this politically sensitive area, the report says, is slowing the development of better methods of contraception, better techniques to preserve endangered species and more cost-effective methods of food production.

At present, embryo and fetal research require the approval of the government's Ethics Advisory Board (EAB). But the board has has not been reconstituted since its charter expired in 1980. The IOM report complains that the eight-year-old ban on the use of federal funds for this kind of research means that more is now known about reproduction in commercially valuable animals such as cattle than in humans. Moreover, the clinical practice of IVF and embryo transfer is outstripping its scientific foundations.

After the renewal two weeks ago of the ban on research involving the transplantation of fetal tissue into humans (see *Nature* 342, 105; 1989), there is little optimism that any steps will be taken to revive the EAB. The IOM recommends that if politics paralyses the existing review mechanisms, then a nongovernmental organization, along the lines of Britain's Voluntary Licensing Authority, should be established to develop guidelines for embryo and fetal research.

But in addition to the political pressures, the report says that the lack of vocal advocacy groups to fight for major increases in federal support, the lack of communication between researchers in the different fields of reproductive biology and the lack of research material for experiments in humans and other primates all contribute to the slow progress in this field and to the low success rates of IVF and embryo transfer.

To improve the safety and effectiveness of the techniques used, the IOM suggests that the professional societies should establish a mechanism to collect and monitor data from clinical centres.

CREATIONISM IN TEACHING

Small changes, big fuss

San Francisco

AFTER months of public debate, the California Board of Education last week approved new curriculum guidelines that give evolution a more central place in science education. But some last-minute concessions to creationists led to very different accounts of the decision's significance in national and in regional news.

At issue were changes in the wording of the science framework that were negotiated in the past few weeks to guarantee the board's approval. The board vote attracted widespread national attention because California controls about 11 per cent of the country's elementary and junior high school textbook market, and its curriculum guidelines — to which publishers must conform — are considered to be influential in setting national standards. The guidelines also influence high school texts, even though the state does not develop an approved list.

The new framework will take effect from 1992 as part of a curriculum overhaul that California undertakes every seven years. Its implementation follows months of public debate over the place of creationism in the science curriculum, which culminated in a public hearing last October.

After that hearing, some board members insisted on several changes to appease Christian fundamentalists. A sentence was deleted that declared that "there is no scientific dispute that evolution has occurred and continues to occur; this is why evolution is regarded as a scientific fact." And phrases were added to the guidelines stating that "some people reject the theory of evolution purely on the basis of religious faith" and that these "personal beliefs should be respected and not demeaned". These changes were heralded by both the *New York Times* and ABC television news as an important victory for creationists, but the *San Francisco Chronicle* referred to the revised guidelines as "a blueprint for teaching science that emphasizes evolution and relegates creationism to social science classes".

But both sides in the dispute agreed that the last-minute changes were relatively minor. Dan Chernow, chairman of the state's curriculum commission, said that while he was disappointed at the changes, he believed that they are "meaningless". And a spokesman for the California-based Traditional Values Coalition said the group was glad for the modifications but called them "crumbs". The revision leaves largely intact repeated references to evolution's fundamental importance to science. For example, the last six words were added to the statement that "the particular case of 'creation science' or 'scientific creationism' has been thoroughly studied and rejected by the leading scientific societies as qualifying as a scientific explanation". Left unaltered is the declaration that "evolution is the central organizing theory of biology, and has fundamental importance in other sciences as well. It is no more controversial in scientific circles than gravity or electricity is."

Such statements significantly stengthen previous guidelines, which made it clear that evolution must be taught but offered no hints to teachers or school officials on dealing with its role in the controversy surrounding creation theory. The new document addresses this shortcoming, noting in part that teachers "should make it very clear that from the scientific perspective, evolution, like other scientific topics, does not bear on an individual's religious beliefs. Science is not theistic, nor is it atheistic; it does not presuppose religious explanations." Chernow said creation theory should be discussed along with other religious issues, either in the history and social science curriculum or the English and language arts curriculum.

Robert Buderi

ANTARCTIC ASTRONOMY

Cerenkov telescope for the South Pole

Washington

PHYSICISTS from Purdue University and the University of Wisconsin at Madison will be travelling south next month to begin a three-year project that will see construction of the first optical telescope, albeit an unconventional one, at the South Pole. An array of ten 1-metre mirrors will be set out on the ice to look for flashes of light caused by ultra-high-energy particles shooting through the upper atmosphere.

For a number of years, researchers from the University of Leeds and the Bartol Institute at the University of Delaware have been operating an air-shower detector at the South Pole (see *Nature* 340, 192; 1989). This device registers the cascade of debris created by a high-energy particle hitting an atom in the upper atmosphere. The Purdue–Wisconsin group will use an alternative detection method which searches for the Cerenkov radiation emitted by a charged particle moving through a refractive medium such as air.

According to James Gaidos of Purdue, the first goal of the Antarctic project is to demonstrate that optical-quality mirrors will work successfully in the extreme climate. The prototype mirrors for the Purdue–Wisconsin telescope are backed with heating elements to keep their surfaces a few degrees above the air temperature, which should prevent condensation and fogging.

David Lindley

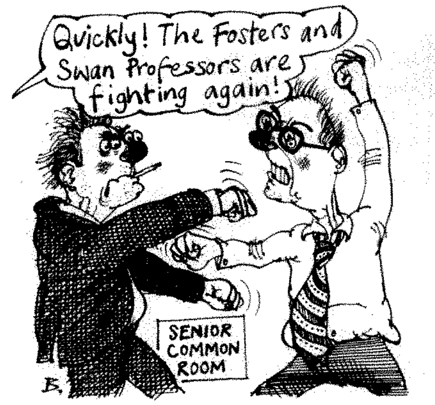
INDUSTRIAL SPONSORSHIP

Research for sale

Sydney

A DISPUTE at Melbourne University over a proposal for commercially sponsored professorial appointments has cast academic freedom and industrial needs as enemies. The university intends to create a new category of position by which private companies would select researchers and finance a university chair for them. The idea follows the recommendation of a report from a working party headed by the university's vice chancellor, David Penington, which says that corporate-funded appointments are necessary because the university has run out of money to create professorial appointments in new fields.

The sponsored professorial fellows would be appointed at the request of the donor company, without being subject to competitive selection. Nevertheless, Penington says that "for each corporate-backed professorial chair the University council must be satisfied that there are no strings attached. If a company wants to donate funds to the university to take on a particular individual, we would be foolish to appoint anyone else. We will, however, make sure of the calibre of the appointee." But the Federation of Australian University Staff Associations (FAUSA) is unhappy with the university's proposed safeguards. FAUSA believes that people appointed at the donor's behest may be reluctant to participate in research that the donor does not approve.



Quickly! The Fosters and Swan Professors are fighting again!
SENIOR COMMON ROOM

"If we give up academic independence and criticism for the money these corporations will bring in then the price is too high", says Ralph Hall, president of FAUSA. But Penington disagrees: "We must develop links with industry if research and development in Australia is to flourish."

Correction

Dr Gerrit Viljoen, the South African Minister for National Education, was professor of Greek at the University of Pretoria before becoming rector of the Rand Afrikaans University in Johannesburg (*Nature* **342**, 8; 1989). ☐

Freedom to conduct research

Sir—The near coincidence of the publication of letters from Donald Kennedy (president of Stanford University; *Nature* **341**, 180; 1989) and Norman R. Saunders of Southampton (*Nature* **341**, 99; 1989) prompts us to write. The former was in regard to Alex Comfort's claim that academics generally show cowardice in the face of external attack, while the latter dealt in part with the inappropriate comments of Clive Hollands (*Nature* **339**, 248; 1989) about a paper from the INSERM group on development of the primate visual system (*Nature* **337**, 265–267; 1989). We were beginning to think that Colin Blakemore (*Nature* **339**, 414; 1989) was the only scientist in Britain with the courage to speak out on an issue of fundamental importance to all scientists: namely, the freedom to conduct research without unwarranted obstruction or meddling. The reticence of scientists on both sides of the Atlantic to speak out in response to attacks by antivivisectionists such as Hollands tends to confirm Comfort's assertion.

We, too, question the propriety of a member of Britain's Animal Procedures Committee (APC) passing moral judgement on research he apparently knew little about in such a public forum as the Correspondence pages of *Nature*. At the very least, Hollands' credibility in terms of being seen as fair-minded in carrying out his duties on the APC has been compromised. Further, Hollands' decision to identify himself in the letter as a member of the Committee for the Reform of Animal Experimentation is troubling, and raises the question: is it appropriate for members of animal research 'reform' groups to serve on committees that regulate animal research? Do we really want foxes minding our research henhouses?

We do not question the necessity of regulating animal research, nor do we question the desirability of having as members of regulatory committees people who are truly concerned about animal welfare. Indeed, everyone who works with animals in any way should be concerned with their welfare, and happily the vast majority of scientists are so concerned. Our apprehension lies with empowering 'false moderates' who cloak their true antivivisection/antiscience agenda with euphemisms. Is this paranoia? We think not. As you point out in your leading article (*Nature* **339**, 491; 1989), conditions for and treatment of animals in research laboratories are improving, in part because of the clamour made by animal activists, many of whom claim to be concerned only with improving welfare. But the hypocrisy of this claim is well illustrated by recent experiences of our university and nearby Stanford. Both universities have been making great efforts at considerable cost to replace antiquated research facilities with state-of-the-art laboratories that will greatly improve the animals' environment. Nevertheless, these changes have been met by the animal 'welfare' advocates not with appreciation but with lawsuits and ever-increasing pressure to halt construction. It seems that every new regulation, stipulation or increased cost of doing animal research is viewed by the antivivisectionists as a victory, and causes them to redouble their efforts to halt such research by whatever means they choose to use. For the 'moderates', it means more lobbying for more expensive and restrictive regulations; for the extremists it means vandalism, theft, arson, bombs and death threats (so far). The silence of the vast majority of scientists on this issue may ensure successs for the antivivisectionists, and once again, in the words of Dr Mary Putnam Jacobi when she testified in 1900 against a bill that would have curtailed animal research in the District of Columbia, we shall see "the domination of knowledge by ignorance".

Charles S. Nicoll
Sharon M. Russell

Sir—The US Department of Agriculture (USDA)'s "dramatic about-turn" allowing research institutions "themselves to decide how to meet the required standards" of animal care (*Nature* **341**, 6; 1989) will add to the already substantial abuse of animals in laboratories. As it is, USDA officials rarely inspect laboratories more than once a year, if that. Violations of the Animal Welfare Act often go undetected, and if they are reported, there may be no follow-up to ensure compliance with the law. Animal protection organizations have exposed blatant violations and abuse that would otherwise still occur.

USDA's authority over laboratories needs to be strengthened, as does the Animal Welfare Act. Allowing researchers to police themselves will result in conditions that benefit the research budget, not the animals.

ECU too

Sir—Fred Hoyle (*Nature* **341**, 380; 1989) finds that the term ECU (European Currency Unit) induces pictures of infinities of little grey men in a very large grey building in his mind. If he respells it, he will find the image quite changed.

The word "ecu" sounds to me like something small, hard and shiny (for example money). It is pronounceable in every European language (with the obvious exception of Greek, which does not have a "c"), and it is short enough to require no further abbreviation.

Provided it does not mean anything foul or ridiculous in any European language, why look further?

Nature conservancy

Sir—As the British government's proposals to split up the Nature Conservancy Council (NCC) will undoubtedly generate much public debate during the next 18 months or so, I should like to correct some inaccuracies in Ben Webb's recent article (*Nature* **341**, 94; 1989).

First, NCC has no statutory responsibility for archaeological sites. Its remit covers the conservation of flora and fauna as well as features of geological or physiographical importance.

Second, before 1973, the then Nature Conservancy did carry out research, but following the formation of NCC this function was handed over, in part only, to the Institute of Terrestrial Ecology (ITE). But NCC's Chief Scientist's Directorate (CSD) coordinates or conducts a wide range of research and survey work necessary for NCC to exercise its diverse functions throughout Great Britain. To say that those opposing the government's proposed reorganization are unlikely to "seek to put the clock back to when NCC had a research capability of its own" is misleading, NCC utilizes such a research capability today. Indeed, the CSD provides the science base and overview upon which many areas of the NCC's work are justified and built.

Third, while Webb focuses on the need for plans to encourage farmers to take into account environmental considerations, no mention is made of other land uses and development pressures. The forthcoming debate will by no means linger on the farming community; many of the problems of conservation in Great Britain today are caused by other socio-economic factors related to industrial and residential development, transport and infrastructure provisioning, forestry and recreational pressures on seminatural and other habitats of importance for wildlife.

NEW Titles from Wiley•Liss

Receptor Biochemistry and Methodology, Volume 14

THE USE OF HPLC IN RECEPTOR BIOCHEMISTRY

ANTHONY R. KERLAVAGE, EDITOR

The Use of HPLC in Receptor Biochemistry offers a concise background in HPLC methodolgy and includes illustrative examples of some of the key advances made in the receptor field through application of this chromatographic technique. A brief historical overview puts into perspective the specific state-of-the-art of HPLC laboratory applications that are contained in the book's chapters.

ISBN 0-471-56231-9 • LC 89-12308 • Publication: November 1989 • Size: 7 x 10 • 266 pages, 113 figures • $96.00

Modern Methods in Pharmacology, Volume 5

PHARMACOLOGICAL METHODS IN THE CONTROL OF INFLAMMATION

JOSEPH Y. CHANG AND ALAN J. LEWIS, EDITORS

This book offers a detailed examination of *in vitro* and *in vivo* models and methodologies used in the study of inflammation. Covering a broad spectrum of topics, this comprehensive volume illustrates the important role that laboratory research models and their related, practical experimental protocols play in inflammation research, as well as in the development and therapeutic evaluation of new anti-inflammatory and anti-rheumatic drugs.

ISBN 0-471-51764-X • LC 89-8012 • Publication: August 1989 • 500 pages, $98.00

Frontiers of Clinical Neuroscience, Volume 7

ASSESSMENT OF THE BEHAVIORAL CONSEQUENCES OF HEAD TRAUMA

MURIEL D. LEZAK, EDITOR

Written in a non-technical, readable style, **Assessment of the Behavioral Consequences of Head Trauma** offers clear guidelines for the evaluation, care, and treatment of head trauma patients. These guidelines take a multidisciplinary approach to head injury management which will prove useful to clinicians in a variety of specialties. The volume is organized to reflect the course of treatment head trauma patients undergo from emergency stages to long term care.

ISBN 0-471-151623-6 • LC 89-8113 • Publication: August 1989 • Size 7 x 10 • 26 figures • 224 pages, $79.50

Frontiers of Clinical Neuroscience, Volume 8

NEUROBIOLOGY OF PANIC DISORDER

JAMES C. BALLENGER, M.D.

Neurobiology of Panic Disorder is designed to capture the excitement of this rapidly evolving field in neuropsychiatry. Featuring vital data obtained during the last five years, this informative volume comprehensively covers the neurobiological aspects of panic disorder, with an emphasis on mechanistic and preclinical studies.

ISBN 0-471-56210-6 • LC 89-12404 • Publication: November 1989 • 280 pages, $96.00

HETEROSEXUAL TRANSMISSION OF AIDS

NANCY J. ALEXANDER, HENRY L. GABELNICK, AND JEFFREY M. SPIELER, EDITORS

Heterosexual Transmission of AIDS examines the sexual mechanisms of transmission of this viral infection, including HIV interactions with sperm, semen, and cervical and vaginal secretions. It explores the principal risk factors in the heterosexual transmission of HIV and how sexual behavior changes the risk of HIV transmission. The book offers authoritative information on the routes of HIV transmission in heterosexuals, and discusses the impact of specific contraceptive methods in controlling the spread of disease.

ISBN 0-471-56208-4 • LC 89-22625 • Publication: December 1989 • approx. 466 pages, price not set

ADVANCED IMMUNOCHEMISTRY: SECOND EDITION

EUGENE D. DAY, PH.D.

The second edition of **Advanced Immunochemistry** contains the kind of information necessary to further the biotechnological development of advances in molecular and cellular immunology. Completely rewritten and updated, the text offers more than a review of the major principles of modern molecular immunology—it provides a comprehensive reference on both the structure and function of the immunoglobulins, and a mechanistic basis for understanding the complexities of immune responses.

ISBN 0-471-56686-1 • LC pending • Publication: January 1990 • Size: 7 x 10 • 338 figures • approx. 686 pages, price not set

Bachem brings the price of high-quality peptides down to earth.

At Bachem, we believe our customers shouldn't have to pay high prices in order to get high-quality products.

That's why in the new Bachem catalog you'll find peptides of the absolute highest quality at the absolute lowest prices.

The 1989-1990 catalog features an extensive line of bioactive peptides and related products – more than ever before — including a wide selection of synthetic peptides, recombinant growth factors, and synthetic intermediates. Hundreds of new products. Thousands of reduced prices.

So call now for your free copy of the new Bachem 1989-1990 Catalog of Fine Chemicals. Discover page after page of high-quality peptides at prices that aren't sky-high.

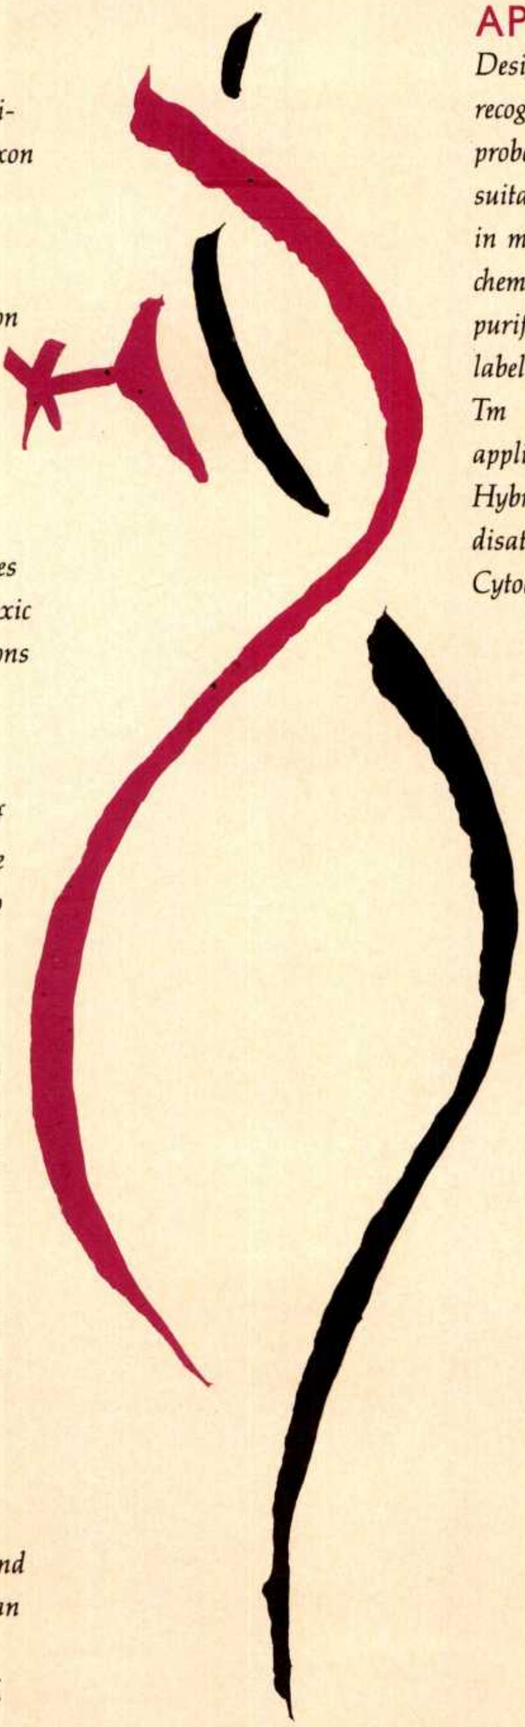
NEW DNA PROBES

(From the people who gave you Designer Genes™)



Human G-CSF

G-CSF stimulates neutrophilic granulocyte colony formation in semi-solid agar. Probes are available to exon 2, 3, 4 and 5.

Human GM-CSF

GM-CSF stimulates the proliferation and differentiation of specific bone marrow precursor cells. Probes are available to exon 1, 2, 3 and 4.

Human TNF ∝

TNF∝ has a wide range of activities on various cell types including cytotoxic functions. Probes are available to exons 3, 4A and 4B.

Human TNFß

TNFß shows most of the activities of TNF∝ and is thought to act via the same receptor. Probes are available to exon 3, 4A, 4B and 4C.

Rat c-fos

The c-fos protein may play a role in nuclear events associated with signal transduction. The probe hybridises to the 5′ region of the gene.

Rat Somatostatin

The somatostatin peptides inhibit the secretion of many different hormones. The probe hybridises to the SS-14 portion of the gene.

Rat Neuropeptide Y

NP-Y is one of the most abundant and widespread peptides in the mammalian nervous system. The NP-Y probe hybridises to exon 1 of mature NP-Y.

APPLICATIONS

*Designer Probes™ from British Bio-technology recognise certain unique exons of genes. As the probes are antisense sequences they are also suitable for detecting the corresponding regions in mRNA. These probes are single-stranded, chemically synthesized and supplied ready purified with recommended protocols for labelling. The probes are of defined length and Tm and are suitable for the following applications. *Northern and Southern Hybridisation *Colony & plaque Hybridisation *In situ Hybridisation *Dot-blot & Cytodot Hybridisation.*

PROBE COCKTAILS

Exon specific Designer Probes™ allow the identification of particular gene regions. The exons selected are all contained in the region coding for the mature forms of the proteins. Also available are Probe Cocktails which consist of an equimolar mixture of exon specific probes. Probe Cocktails will pick up a combination of different regions of the gene and therefore show a higher level of sensitivity than individual probes. Probe Cocktails can be used for all the applications listed above.

MOLECULAR GENETICS

False start on manic depression

Miranda Robertson

MOST of the presentations at *Nature*'s conference in Boston, held last week, were a startling reflection of the pace of progress in the understanding of the genetic mechanisms of complex processes. The one conspicuous reversal, candidly acknowledged by Ken Kidd (Yale University), was in the genetics of psychiatric disease.

Readers of *The New York Times* may already be aware that the linkage reported in *Nature* two years ago[1] between manic depression and a locus on chromosome 11 is now acknowledged probably to have been spurious. The events that led to this conclusion are described, by a group including many of the authors of the original report, on page 238 of this issue[2], and were discussed at the meeting by Kidd who is co-author on both papers. At the end of his presentation, David Baltimore (Whitehead Institute) voiced the question that must have been left in many people's minds: "Setting myself up as an average reader of *Nature*", he asked, "what am I to believe?". What follows is an attempt to enable readers to answer the question for themselves.

A picturesque feature of the original study was the choice of the Amish community of Pennsylvania for analysis. The Amish are no more prone to psychiatric disease than other groups, but they have three advantages as subjects for the investigation of complex genetic traits. First, they have large families whose members do not disperse. Second, the restrictive rules they live by reduce confounding environmental variables such as drugs and drink. Third (and crucially), the Amish are relatively inbred, which increases the probability that an abnormal phenotype running in a family will be traceable to the same gene in all affected members.

The claim of the 1987 paper was that manic depression in a large Amish pedigree was linked to two marker genes, the *Harvey ras* oncogene and the insulin gene, known to be in the same region of the short arm of chromosome 11. Neither of these genes was itself implicated in the disease, nor was any other gene actually identified as the cause of the disorder: the claim rested upon the consistent inheritance of specific and recognizable variants of the two marker genes with the propensity to develop manic depression, and on a calculation of the probability that this co-inheritance could occur purely by chance. The traditional measure of this probability is the LOD score (LOD standing for the log-of-the-odds ratio), and the traditionally acceptable LOD value is 3, corresponding to a probability of 0.05 against the chance occurrence of the observed pattern of co-inheritance. The LOD score for the linkage of a chromosome 11 locus to manic depression was comfortably more than 4.

For any disorder, the assessment of linkage is complicated by the possibility of recombination events that may separate the marker from the gene and that become more likely the greater the distance between the two (this distance being of course unknown). For psychiatric disorders the calculation is further complicated by the likelihood of incomplete penetrance, which means that some individuals with the predisposing gene will fail to develop the disorder. Both factors must be taken into account in calculating linkages to psychiatric diseases.

Thus the conclusion that a gene on chromosome 11 could predispose to manic depression was calculated on a delicate balance of uncertainties. Two developments have now upset that balance. First, two people in the original Amish pedigree have become manic depressive in the absence of the putative markers of predisposition; second, an additional branch of the original pedigree shows negative evidence of linkage. This could mean that there are two genes instead of one predisposing to manic depression in the pedigree; but the simplest explanation is that the apparent linkage to a chromosome 11 locus was in fact just chance.

According to Kidd, chance may also account for a second genetic linkage, more recently reported by Hugh Gurling's group[3] which has published evidence implicating a locus on chromosome 5 in predisposition to schizophrenia. The conclusion in that case was based on two markers which, as Lander[4] remarked at the time, were uninformative for many members of the five families analysed, where the same marker variants were carried by both the affected and the unaffected parent.

In an attempt to find a marker that will distinguish the parental chromosomes in these cases, Gurling has since tested a third chromosome 5 marker which, as it turns out, shows less evidence of linkage than either of the other two. This could mean that the third marker is more distant from the putative schizophrenia locus than the others, allowing more recombination between the marker and the gene; but in fact Kidd maps the third marker in between the other two, ruling out that explanation. This leaves us with no persuasive evidence linking any psychiatric disease to a single locus and brings us back to Baltimore's question.

It is neither necessary nor justified to conclude from these reversals that there simply is no single gene capable of predisposing some individuals to psychiatric disease. Studies of identical twins have already provided very strong evidence, especially in the case of schizophrenia, for an important genetic component. There is on the other hand every reason to expect the predisposing genes to be hard to identify, for reasons that can be illustrated by the remarkably successful recent attempts at analysing the complex multifactorial genetics of predisposition to coronary heart disease.

The work on cholesterol metabolism in particular was discussed by Gerd Utermann (University of Innsbruck), who has been investigating the effects of plasma lipoprotein polymorphisms on coronary heart disease in people already known to be at risk through a mutation in one of their low-density lipoprotein (LDL) receptor genes. People who are homozygous for such mutations never escape heart attack. Heterozygotes on the other hand may have heart attacks by the age of 40, or they may be quite unaffected. What Utermann has been able to show is that polymorphisms in plasma proteins that affect cholesterol levels can account for much of the variation in effect of the LDL receptor mutation on heterozygotes.

In this case several interacting genes affecting the uptake and disposition of lipids can be seen to contribute to the risk of heart disease in such a way that no one mutant gene or polymorphic variant would reliably be inherited with the disease. We may expect the genetics of psychiatric disease to be at least as complex as those of cholesterol metabolism. But in the absence of a good biochemical clue to what genes may be involved, they will be much harder to trace. The hope has been that the high incidence of specific psychiatric disorders in inbred families reflects the existence of a single, strong, predisposing allele. If in fact it is necessary to seek linkage to more than one gene in such families, there are techniques that would make this possible[5]; but a high-resolution linkage map of polymorphic markers for the human genome would be needed for a reasonable chance of success, and in the view of many this should be a priority for the human genome project.

In the meantime, readers of *Nature* are entitled to be sceptical about reports of psychiatric disease linkages at LOD scores of less than 6. But they should have no reason to doubt the existence of genetic predisposition to psychiatric disease, nor the ability of molecular geneticists eventually to identify the genes responsible. □

STATISTICAL PHYSICS

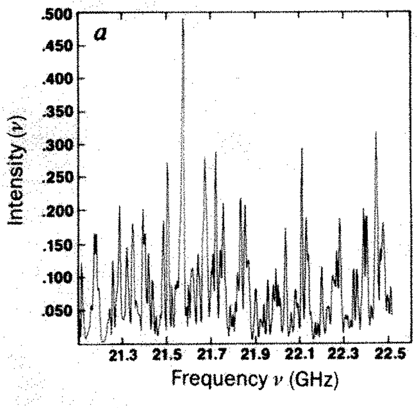
Microwaves in random media

J. B. Pendry

A DIFFICULT statistical problem, as yet unsolved, concerns the motion of waves in random media. The problem can be compared with the kinetic theory of gases, one of the great achievements of physics. Newton's equations of motion were redeveloped to formulate equations describing the macroscopic properties of the gas. Crucial to the process was the interplay between theoretical insight and experimental stimulation. In the case of waves in random media experimental results will be equally critical. A recent experiment by N. Garcia and A. Z. Genack (*Phys. Rev. Lett.* **63**, 1678–1681; 1989) provides a veritable paradigm of the problem for theorists.

It is no accident that the kinetic theory of gases was developed long before theorists felt able to tackle waves in random media. A large sample of gas can be characterized by macroscopic quantities such as temperature, pressure and volume, which are well defined and whose statistical fluctuations can be neglected. Not so for waves in a random medium: the further waves penetrate into a disordered system the more extreme become the intensity fluctuations. This is true for any degree of disorder; but for strong disorder, the wave is essentially scattered within its own wavelength and the resulting wavefield is even more statistically complex. The fluctuations cannot be ignored and must be included in any theory.

An example of these fluctuations is given in Garcia and Genack's article. The sample consists of uniform half-inch-diameter polystyrene spheres with filling fraction 0.56, contained in a 7.3-cm-diameter copper tube. The wavelength of microwave radiation used was about 1 cm. The spheres fill the tube uniformly, but can still move when the tube is tumbled, providing another statistical configuration. Microwaves are launched from a horn 20 cm in front of the sample and detected by a Schottky diode mounted on a plunger that defines the length through which the microwaves pass. Figure 1*a* shows the transmitted intensity as a function of frequency for a static sample 140 cm in length. Note the extreme fluctuations, which take the form of a series of sharp peaks separated by deep troughs. Tumbling the tube generates a different set of peaks and troughs, but of the same general character.



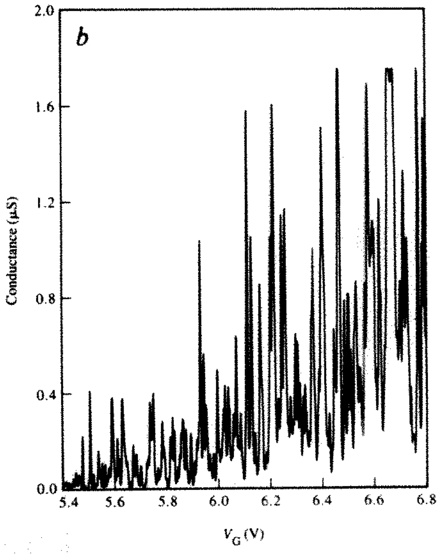


FIG. 1*a*, Spectral intensity fluctuations for microwaves passing through a 140-cm length of tube filled with half-inch-diameter polystyrene balls. *b*, Conductance of a silicon-metal-oxide field-effect transistor as a function of gate voltage measured at 50 mK.

If these results were unique to microwaves the experiment would be a mere curiosity. Let us take a couple of other examples from the pages of *Nature*. A few months ago in News and Views (*Nature* **339**, 581; 1989), I discussed waves in semiconductors: in that instance the waves were, of course, electrons. When the semiconductor is disordered, the conductance–voltage plot may look like that shown in Fig. 1*b*. These data (A. B. Fowler, J. J. Wainer & R. A. Webb *IBM J. Res. Devel.* **32**, 372–383; 1988) are for a silicon-metal-oxide field-effect transistor at 50 mK. The similarity in form to the microwave transmission experiments is striking because the origin of the fluctuations is the same: waves in random media.

An earlier example comes from W. H. Munk and G. O. Williams (*Nature* **267**, 774–778; 1977). This paper discussed the transmission of 406 Hz acoustic signals through the ocean. The distances in question were very long — of the order of 1,000 km — and the disorder results from mesoscale fluctuations in the ocean's currents. A simulation of the acoustic transmission through a typical path, plotted in the complex plane (Fig. 2), reveals both amplitude and phase fluctuations. It is clear that extreme fluctuations are again involved. A related phenomenon is the fading of radio waves in the ionosphere. An example closer to common experience is provided by the propagation of a thunder clap across a random landscape: close to the strike a single sharp crack is heard; farther away the Fourier components in the crack pass through the random acoustic filter provided by a disordered landscape, and recombine to produce the characteristic rumble whose long duration bears witness to the narrow bandwidth of the transmission peaks.

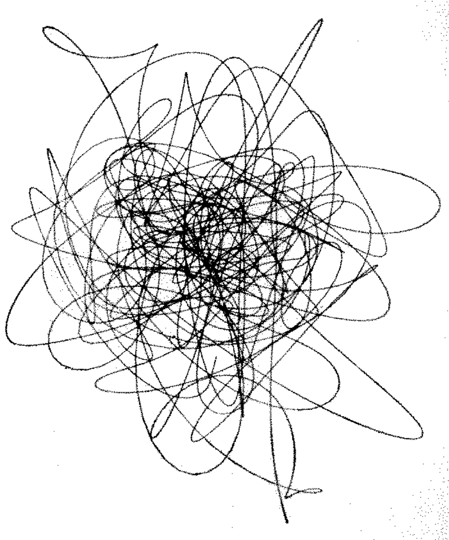

FIG. 2 Acoustic transmission simulated for transmission through approximately 1,000 km of fluctuating ocean at a frequency of 406 Hz. The distance from the origin shows the intensity; the angle, the phase.

Of these examples, the electronic instance is the most important, with its consequences for problems likely to be encountered in the construction of small low-dimensional devices. Despite the rich variety of experiments on disordered electronic systems, there are some problems involved in comparing them with the current imperfectly developed theories. First, the scale of electronic wavelengths is such that probes on this scale have yet to be developed. Second, electrons are mutually interacting particles and the complication of treating disorder at the same time as electron–electron interactions is one that the theorist would rather be without until a clear understanding emerges of the effects of disorder alone. Third, electronic experiments are, as a rule, made on a single device. Switching to another device is often time consuming and it is impossible to perform ensemble averaging over specimens. This can be a great disadvantage where strong fluctuations are important.

The microwave experiment eliminates all these objections and should prove an ideal test bed to knock on the head unsuccessful theories, and to help good ones.

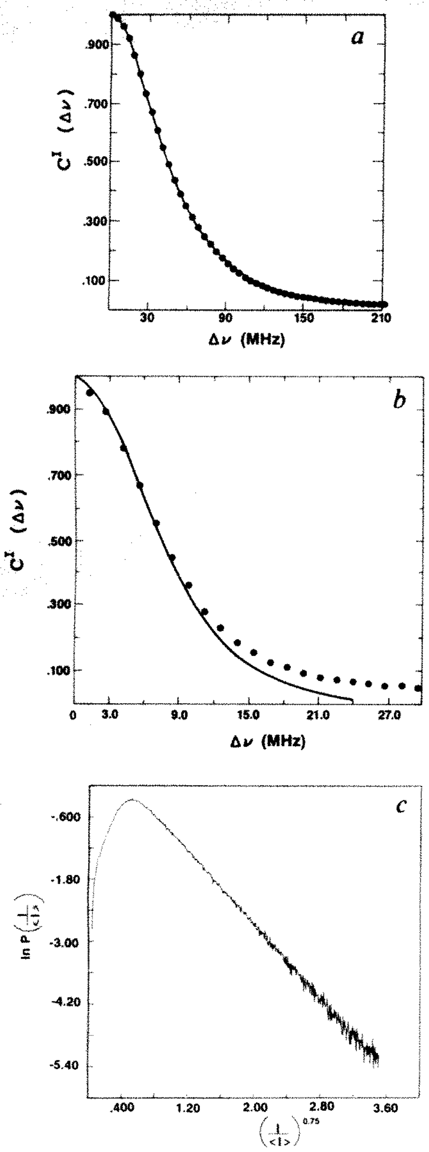

FIG. 3 The correlation function $<I(\nu)I(\nu+\Delta\nu)>$ for transmitted intensity at two frequencies separated by $\Delta\nu$. The solid line shows the theoretical fit. *a*, Length of tube is 30 cm; *b*, length of tube is 140 cm. In the longer sample, strong-disorder effects begin to assert themselves and the correlation function shows a high-frequency tail not explained by the theory. *c*, The probability distribution of intensities transmitted through a tube of length 140 cm, plotted against $(I/<I>)^{3/4}$.

Figure 3 provides an instance of this process at work. It shows intensity-intensity correlation functions from Garcia and Genack's paper where the intensities are measured with frequency separation $\Delta\nu$. Theory developed for the weak-scattering limit fits the data very well for short samples (Fig. 3*a*), but not for longer ones in which the scattering builds up to large values (Fig. 3*b*). Another puzzle is shown in Fig. 3*c*, a plot of the probability distribution of transmitted intensities. A curious exponent of 3/4 is found for the dependence of $\log(P(I))$ on I. So far theory does not have an explanation.

Theorists are not completely at sea with these problems. Even for strongly disordered samples we have a general understanding of why strong fluctuations occur. Disorder strongly inhibits the passage of waves through the medium, and therefore it is possible for resonant cavities to form at random within the medium. Waves can be trapped in these for a long time before tunnelling out. The longer they are trapped, the sharper the resonances, as we understand from conventional theory of resonances, so that a thick, strongly disordered sample will have more sharp resonances than a short, weakly disordered one. The resonances play an important role in the transmission properties of the sample: waves whose frequency is degenerate with a resonance show enhanced transmission. The sharp spikes seen in Fig. 1*a* betray the presence of resonant cavities within the sample. The statistics of transmission through strongly disordered samples is the statistics of these resonances.

A whole series of new experiments is opened up to us. What are the effects of exchanging the one-dimensional tube with a two-dimensional sheet? Can the reflection coefficient be measured? And how do the resonances beneath the surface affect the noise characteristics of the reflected signal? Can a more complex medium be studied, for example one in which the dielectric medium has lower symmetry and shows optical activity? What about the higher moments of the transmission coefficient? The answers to these questions are eagerly awaited. ☐

J. B. Pendry is in the Blackett Laboratory, Imperial College of Science, Technology and Medicine, London SW7 2BZ, UK.

PROTEIN STRUCTURE

Chaperones, paperones

Joe Sambrook and Mary-Jane Gething

FOR the past several years, chaperone proteins have been a valuable commodity for speculators in protein function. Identified in most organelles of eukaryotic cells, chaperones bind to newly synthesized polypeptides and apparently stabilize them until they are assembled into their correct native structure[1,2] or until they are transported into another cellular compartment[3]. With the description by Holmgren and Bränden on page 248 of this issue[4] of the first three-dimensional structure of a chaperone protein, albeit one that is bacterial and rather unusual in several respects, comes a result that was not predicted by any of the speculators: the two structural domains of the protein that seem to carry out the chaperone function resemble immunoglobulin domains.

Most of our knowledge about chaperones has come from biochemical and genetic studies carried out in eukaryotic cells[3,5-8]. As far as we know from these studies, chaperones are not true catalysts of protein folding. They are, for example, unable to catalyse the formation or isomerization of covalent bonds in the target proteins. In these respects, chaperones differ from conventional enzymes such as protein disulphide isomerase, prolyl isomerase or prolyl hydroxylase, that modify the structure of newly synthesized proteins. In addition, chaperones can remain attached to their target proteins for far longer than an enzyme would be expected to interact with its substrate[9]. Finally, many chaperones can interact with a wide variety of target proteins *in vivo*[1,2] and with synthetic peptides of diverse sequence *in vitro*[10]. These targets seem not to have any amino-acid sequences or structural motifs in common. Diversity on such a scale is not found in substrates for conventional enzymes.

Most of the experimental evidence is, instead, compatible with the idea that chaperones stabilize segments of polypeptide that might otherwise serve as local centres for intra- or interchain aggregation or denaturation. In this way, chaperones might provide the time needed for thermodynamic forces to drive folding of large and complex proteins to completion. According to this idea, chaperones would increase the efficiency of folding and assembly of newly synthesized proteins, but would not necessarily expand the repertoire of interactions that occur between polypeptide chains in the final protein. Alternatively, they might also maintain parts of the nascent polypeptide chain in configurations that could eventually be converted into a wider variety of shapes and surface than would otherwise be possible. Chaperones would therefore not only increase the efficiency of protein folding but would also extend the range of interactions both within and between polypeptides. A simple analogy is the lock and key structures that hold together poppet heads in a child's necklace. Although such interlocking structures are unknown in proteins, there are many examples of interactions between deeply convex and concave surfaces. Chaperones may serve as a mechanical jig to hold segments of a polypeptide chain in a state that allows complex surfaces to form. Perhaps, without chaperones, only a subset of complex topological surfaces could be generated by interaction between 'pre-assembled' polypeptides.

Holmgren and Bränden's crystal structure, which provides a new window on chaperone mechanisms, is of the PapD protein isolated from the periplasmic space of *Escherichia coli*. Strains of *E. coli* that cause nephritis carry special pili (aptly named P pili) that allow the bacteria to adhere to digalactoside residues on the surface of cells lining the urinary tract[11,12]. These pili, which project through the outer bacterial membrane and cell wall, consist of approximately 1,000 protein subunits and are assembled in the periplasmic space from components that have been translocated across the inner bacterial membrane. The shaft of each pilus consists of repeating units of a single protein (PapA), whereas the tip consists of three proteins, PapE, PapF and PapG[13], the last of which carries the digalactoside-binding activity of the pilus[14].

The single operon that encodes all of these proteins also encodes two accessory proteins that are not incorporated into the pilus but are required for its formation[12,15]. One of them, PapC, appears to form a channel in the outer bacterial membrane through which the growing pilus emerges[16]. The other, PapD, is a periplasmic protein that forms complexes with subunits of at least two of the proteins (PapG and PapE) before they are assembled into the pilus[17]. Earlier this year, a group of Swedish workers proposed that PapD acts as a chaperone to enhance the postranslational folding and assembly of components of the pilus[18].

Holmgren and Bränden now show that PapD is built from two globular domains, each consisting of an antiparallel structure formed from packed β-sheets. The topology of each domain is the same as that of the constant domain of the immunoglobulins. Whereas there is no significant amino-acid similarity between either of the two domains of PapD and the constant domain of immunoglobulins, the sequence of 239 amino-acid residues can be aligned with the N-terminal 256 amino-acid residues of the Leu-1 human lymphocyte differentiation antigen (also known as CD5). Of the amino-acid residues in the aligned sequences, 26 per cent are identical. The authors propose that PapD and CD5 form a special subclass of the immunoglobulin gene superfamily. Whether or not their speculation that the subclass was dispersed by horizontal gene transfer during evolution turns out to be true, their work provides dramatic evidence of the durability and utility of this type of protein fold.

Chaperone watchers will be most interested in the region of PapD that potentially interacts with its target proteins. The best candidate is the wide crevice between the two domains that contains an exposed hydrophobic patch flanked by basic and acidic residues. In addition, the region linking the two domains perhaps serves as a flexible hinge that can open up to accommodate target sequences of various sizes. The orientation of the target polypeptide within this site is not known, as the PapD molecules crystallized by Holmgren and Bränden are 'empty'. It would be interesting to find out whether PapD, like chaperones such as BiP and HSP70 (ref. 10), can bind oligopeptides of defined sequence and, if so, whether the binding is tight enough to allow crystallographic analysis of PapD-target complexes.

PapD is an unusual chaperone in several respects. It is smaller than most, contains no obvious ATP-binding sites and appears to be more specific in its function. Unlike BiP or other members of the HSP 70 family, which bind to a wide variety of target proteins and perform functions that are indispensable to the life of the cell, PapD binds only to polypeptides encoded by the *pap* operon. Therefore it is not necessary for the survival of *E. coli*, but only for its colonization of the urinary tract. Because the function of PapD is more specialized than that of other chaperones, the potential polypeptide-chain binding site formed between two immunoglobulin-like domains may differ in detail from those of chaperone proteins that fulfil more generalized functions in protein folding and assembly. There cannot, however, be too many ways to form clefts that can accommodate polypeptide segments of varying sequences. Holmgren and Bränden's structure, together with that of the class I major histocompatibility antigen[19,20], provide examples of two ways to solve this problem. It remains to be seen whether other chaperones use similar structural motifs. ☐

OZONE DEPLETION

A dent outside the hole?

Guy P. Brasseur

THE formation of an ozone hole inside the polar vortex over the Antarctic continent each spring (September to November) since the late 1970s has been a cause of wide concern. In a rather provocative paper on page 233 of this issue[1], Proffitt *et al.* suggest that, from August to September, a substantial amount of high-latitude ozone is also destroyed outside the Antarctic vortex, by unidentified chemical processes. This conclusion is reached by an indirect but elegant analysis of simultaneous measurements of ozone, nitrous oxide (N_2O) and reactive nitrogen species (abbreviated as NO_y) made by stratosopheric jet-borne experiments.

Following the discovery of the ozone hole, there were several coordinated measurement expeditions, including the 1987 Antarctic Airborne Ozone Experiment from which Proffitt *et al.* derive their data, in an attempt to elucidate the mechanisms responsible for the depletion. These have revealed that active ozone-destroying forms of chlorine are produced in the lower stratosphere by the conversion of relatively stable molecules such as HCl and $ClONO_2$ on the surface of ice particles in the stratospheric clouds formed in the polar winter (when temperatures drop below −85 °C). The concentration of chlorine monoxide inside the polar vortex during the Antarctic spring is found to be 100 times higher than at midlatitudes: this is sufficiently elevated to destroy much of the ozone in a couple of weeks.

The suggestion by Proffitt *et al.*[1] of early-springtime depletion outside the polar vortex is a surprise because no such mechanism can operate there. The first step in the analysis leading to their suggestion is to note that, outside the chemically perturbed region of Antarctica, there is a persistent linear (negative) relation between the concentration of N_2O and NO_y in the lower stratosphere. The source of nitrogen oxides in the stratosphere is the slowly reactive nitrous oxide, which is produced at the Earth's surface and transported into the stratosphere by air currents. The necessary conservation of nitrogen atoms inside a given air parcel, as the conversion from N_2O to NO_y proceeds, explains the relation between the concentration of these species. The relation, however, does not hold in chemically perturbed regions, where NO_y is efficiently removed by ice particles and by their subsequent sedimentation. Thus, by making use of this relation between N_2O and NO_y, it becomes possible to discriminate between air masses that have been affected by the perturbed chemistry in the region of the ozone hole and those that have not been perturbed.

In the second step of their analysis, Proffitt *et al.* calculate the concentration ratio of O_3 to NO_y along a flight path from California to Chile. If, in the lower stratosphere outside the polar vortex, both ozone and NO_y are not significantly affected by chemistry, this concentration ratio should remain fairly constant. In air masses unperturbed by polar chemistry, this concentration ratio is of the order of, or larger than, 300 at heights of 18 – 21 km at all latitudes, except south of 50° S where it is substantially reduced. The authors conclude that a significant chemical sink must exist in the region between this latitude and the boundary of the chemically perturbed region, located near 65° S. Losses are about 15 per cent in late August and as high as 30 per cent in late September. These losses were not isolated events but were found throughout the period during which observations were made.

These results are consistent with statistical analyses[2] of ozone data obtained in this region. In addition, comparisons between vertically integrated ozone concentrations measured between 1979 and 1988 by the total ozone mapping spectrometer (TOMS) on board the Nimbus 7 satellite also indicate substantial ozone reductions in the Southern Hemisphere outside the chemically perturbed region[3,4]. But, in this case, the depletion was attributed to the dilution in late spring of ozone-poor air originating in the region of the ozone hole. The results presented by Proffitt *et al.* indicate that, even before the polar vortex breaks up, and probably as early as August (before the formation of the ozone hole), an efficient chemical mechanism destroys ozone at high latitudes, south of 50° S. The possibility that ozone is destroyed during the Antarctic winter (as early as June) in the layer where polar stratospheric clouds are present, was recently suggested by Fiocco *et al.*[5].

Despite all this evidence, no definite conclusion can yet be drawn. The number of ground-based Dobson instruments, by which ozone is measured (and which are used to correct some of the satellite measurements), is too small for the data analyses to be sufficiently reliable. Furthermore, the quantitative values reported by Proffitt *et al.* are somewhat marginal and do not show unambiguously that the anomaly in the O_3/NO_y ratio is a manifestation of chemical destruction. The increased value of this ratio they observed over the tropics is not entirely explained.

But alternative explanations for the measurements by Proffitt *et al.* are readily discounted. For example, the vertical exchange of air parcels outside the vortex would alter the local composition. As suggested by the high temperatures and maximum ozone (and NO_y) concentrations observed near 60° S, air parcels should subside in this region. But the O_3/NO_y ratio increases slightly with altitude, so that exchange would give the opposite effect to the one reported. Alternatively, enhanced production of NO_y, which is caused by galactic cosmic rays with maximum efficiency at 15–20 km, would result in a reduced ratio of O_3/NO_y. But this process is confined to a region near the magnetic pole that does not extend out to 50° S.

A chemical process thus seems to affect ozone at high latitudes outside the region where the Antarctic ozone hole appears and before the hole is produced. Further evidence for such an effect as well as an explanation of the processes involved needs, however, to be presented before it can be claimed that a significant chemical ozone destruction is taking place in winter and spring. The concentration of active chlorine outside the vortex is not large enough to account for a 15–30 per cent ozone loss even with the sunlight available at these latitudes during winter, so it seems unlikely that the hole-type loss mechanisms account for the observed ozone destruction. Perhaps heterogeneous chemical processes on the surface of background sulphuric acid aerosols are responsible. Other possibilities are mentioned by Proffitt *et al.*. In any case, it will be interesting to see if similar anomalies in the O_3/NO_y concentration ratio are found in the high-latitude region of the Northern Hemisphere. ☐

PALAEOENVIRONMENTS

No smoke without fire

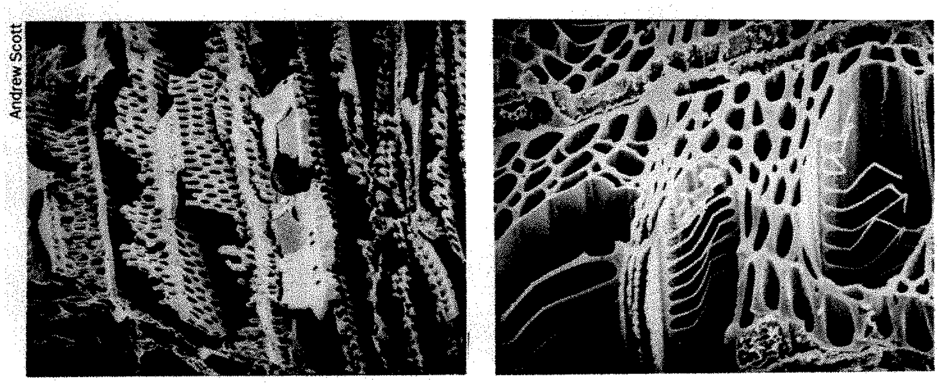
Peter D. Moore

AMONG her many other contributions to science, Marie Stopes, in 1919, analysed the constituents of coal and found particles of black, opaque matter that was chemically inert yet physically fragile. Stopes believed that this material, which she called 'fusain', represented fragments of plant charcoal derived from ancient fires. Fusain, which has subsequently proved to be a common component of coals and many other rocks, has attracted considerable attention in recent years as it could provide evidence of past wildfire frequency and hence of the gaseous and particulate composition of the palaeoatmosphere. Using scanning electron microscopy and reflectance microscopy to examine charcoal generated from contemporary plant material, Scott[1] has now laid the basis for further understanding the origin and significance of fusain.

The source of ancient fusain has been much debated. Some workers considered it to be a product of wet decay, but Harris[2] found that charcoal resulting from modern forest and heath fires bore a strong resemblance to fossil fusain. This observation led Harris to consider the role of fire in Tertiary times as an ecological determinant of vegetation, and as a selective factor in the evolution of Mesozoic flora. The dispersal of carbonaceous fragments through the air depends on settling velocity and hence on particle size. During a cruise across the Atlantic in 1980, Andreae[3] filtered fine particles of carbonized material (2–5 μm in size) from the atmosphere, and found that dispersal was so efficient that the fragment densities in remote parts of the Atlantic were comparable with those in rural continental areas. The presence of a 'soot' layer in clays from the Cretaceous/Tertiary boundary has subsequently raised the question of whether wildfire-generated smoke may have contributed to the change in climate that occurred during this period[4].

Cope and Chaloner[5,6] have used the presence of quantities of fusain in rocks as a basis for the reconstruction of palaeoatmospheres, claiming that, since the Lower Carboniferous, atmospheric oxygen levels cannot have fallen below 30% of their present level (a figure subsequently revised to 60%). This conclusion is based on the oxygen levels that would have been required to support the extensive forest fires that generated the widespread influx of fusain into sediments.

Scott[1] has now extended the experimental work of Harris[2] by scanning electron microscopy of carbonized material generated from a variety of plant parts, such as wood, leaves and flowers (see figure). He finds very close agreement between the experimental and the fossil material in the preservation of detailed anatomical structure of the tissues. Charred material often retains a clear and almost perfect structure, especially in wood samples but also in more delicate organs. Reflectance microscopy has also proved a valuable tool. Wood charcoal and wood-



Andrew Scott

derived fusain have very high reflectance values, whereas charred leaf tissues have lower reflectance. There is also a positive correlation between the temperature of combustion and reflectance. It should, therefore, prove possible to interpret fossil fusains with some degree of precision, both in the location of their source and their mode of origin.

Charcoal in coal is derived from either local wetland forest fires or from a considerable input of charcoal from airborne sources. The possibility of water transport into the site of sedimentation is unlikely for many coals because the coal-forming mires seem to have arisen as ombrotrophic (rain-fed) systems, similar to modern raised bogs, rather than rheotrophic (stream-fed) wetlands. Scott suggests that the origin of fusain could be determined simply by taxonomic analysis. Gymnosperm material is likely to mean upland fires and aerial input, whereas lycopod and fern fusain indicate local fire. The differential production and survival of carbonized particles from the different plants, must, however, be accounted for.

This line of research is promising both as a means of determining whether coal-forming mires were subject to fire (and, by implication, periodic drought), and also as a source of information on the ecological significance of fire in the evolution of plants and the development of vegetation.

CHEMICAL SYNTHESIS

Scaling molecular Everests

John Mann

DURING a 2½ hour lecture in 1972, R. B. Woodward described the first total synthesis of vitamin B12. At that time it was the most complex naturally occurring compound that had succumbed to total synthesis. It had occupied the efforts of an army of chemists on two continents over a period of 12 years (R. B. Woodward *Pure appl. Chem.* **33**, 145–177; 1973; A. Eschenmoser & C. E. Wintner *Science* **196**, 1410–1420; 1977). In the audience that evening at Harvard was a young Japanese chemist, Yoshito Kishi, newly appointed to the staff of the Chemistry Department. He has now scaled his own 'chemical Everest' by synthesizing with his colleagues the structurally complex marine toxin, palytoxin (Y. Kishi *et al. J. Am. chem. Soc.* **111**, 7525–7530, 7530–7533; 1989).

Palytoxin, a product of marine coelenterates of the genus *Palythoa*, is the most toxic non-proteinaceous substance currently known. Its median lethal dose (LD50) is about 0.025 µg kg^{-1} for the rabbit and 0.45 µg kg^{-1} for the mouse. Although the LD50 for man is not known, the toxin was used in the past by native Hawaiians as a spear poison.

Palytoxin was first isolated by the group of R. E. Moore and P. J. Scheuer in 1963. They estimated its relative molecular mass to be around 3,000 (it is actually 2678.5), but the molecular formula of $C_{129}H_{223}N_3O_{54}$ remained in doubt until the gross structure was finally established in 1981 (Fig. 1*d*). An initial problem was classification of the toxin. Most natural products contain repeating subunits derived from acetate or mevalonate or other small building blocks, but such was not the case with palytoxin. The best one can say is that it possesses a highly functionalized fatty acid chain interrupted by monosaccharide residues.

In the mid-1970s, the Hawaiian group (Moore and Scheuer) and a Japanese group led by Y. Hirata used chemical degradation and the newly emerging NMR and mass-spectroscopic techniques to determine the gross structure of palytoxin. As the complexity of the molecule emerged, it became clear that the toxin presented an unprecedented challenge for the synthetic chemist. Kishi accepted the challenge.

First, his group synthesized (1980–82) each of the fragments produced by degradation, thus providing an unambiguous confirmation of the gross structure, and also complementing the stereochemical assignments being made (on the basis of spectroscopic studies) by the other groups. By 1985, they had devised practical routes to eight key building blocks, all in stereochemically pure form; the stage was then set for development of methods for the convergent coupling of these fragments. The successful completion of these efforts is the subject of the two recent papers, and Kishi now has in hand palytoxin acid which lacks only the terminal N-(3′ - hydroxypropyl)-3-aminopropenamide moiety of palytoxin.

There is no doubt that this synthesis could not have been accomplished in the 1970s. It required the revolution in the methods of asymmetric synthesis achieved in this decade, and the contemporaneous evolution of sophisticated two-dimensional NMR techniques to make it possible. The primary value of this latter

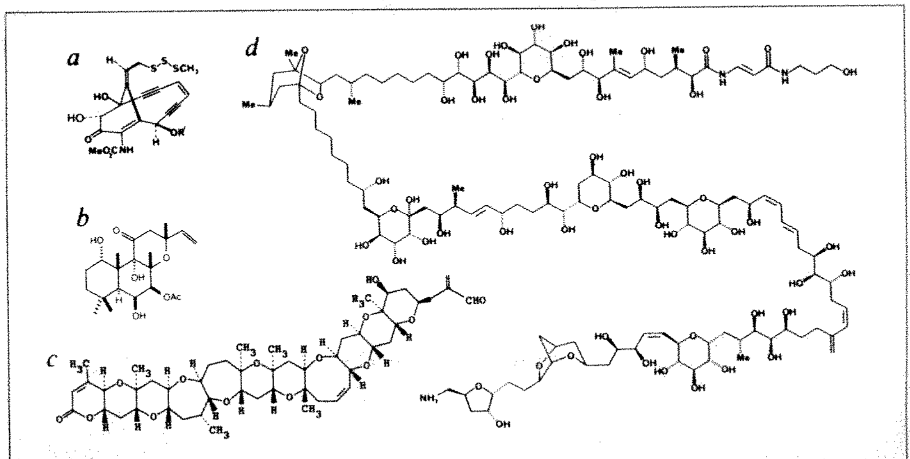

FIG. 1 Structures of palytoxin (*d*) and three other natural synthetic targets (see text).

to lower-crustal depths in the region). Their data also imply that the metamorphism occurred relatively recently — no more than 30 million years ago. Hayob *et al.* interpret the distribution of xenolith localities to indicate that the granulite-grade metamorphic event was regional in extent (at least 100 km^2 in area and perhaps extending for more than a thousand kilometres to the north). The heat source is inferred to be underplated basaltic magma, small volumes of which reached the surface as the xenolith-bearing basanites. The authors emphasize their evidence for the lack of a protracted history of cooling of the xenoliths (to temperatures less than 900 °C), and the fact that basaltic magmatism continues to be active in the region. They use these observations to postulate that granulite-facies metamorphism continues even now in southern North America.

Hayob *et al.* suggest that the lower crust can contain supracrustal rock types, that, in this case, the lower crust is granulitic, that granulite-facies metamorphism can be powered by mantle heat through basaltic underplating away from mountain-building (orogenic) settings, and that these processes are still continuing. None of these ideas or general observations (except for the extreme temperatures and limited retrograde cooling) is uniquely that of the authors. Their contribution lies in documentation and in the recognition of the collective importance of the separate pieces of data. The authors' arguments need some strengthening, particularly by the application of different age-dating techniques to xenolith mineral assemblages and integration with structural, tectonic and geophysical observations. But even as it stands, the evidence is sufficiently strong to make waves in the sea of geological opinion.

In the short term, the debate is unlikely to settle down. Granulite-facies metamorphism does occur over a broad range of conditions (700–1,100 °C, 400–1,500 megapascals, water activity 0–0.7) in varied tectonic settings. This suggests that a great variety of materials and processes are involved. The task ahead is to determine which are actually involved and which are most important. I expect that the underplating mechanism, combined with partial-fusion reactions in the absence of fluids, will turn out to be a principal factor in granulite-facies metamorphism, growth and differentiation of the crust, and the origin of upper-crustal granitic rocks. In an even broader context, I believe that core–mantle boundary instabilities, mantle plumes, anomalous conductivity in the lower crust, continental rifting, flood basalt outpourings and major biological events will all eventually come to be linked with these lower-crustal processes, operating on supracrustal rocks, in the same complex, discontinuous chain of events. ☐

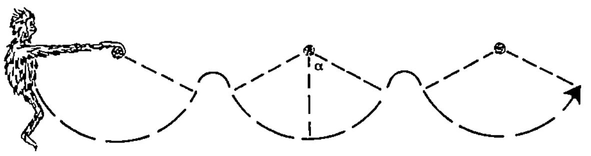
BIOMECHANICS

Gibbons swing stress away

R. McNeill Alexander

A FORCE acting on the end of a bone, parallel to its long axis, sets up stresses that are uniform across each cross-section. A force at right angles to the bone exerts bending moments on it, setting up tensile stresses in one face of the bone and compressive stress in the opposite face. When mammals run, the stresses in their bones are mainly due to bending moments. But when gibbons brachiate, swinging from branch to branch by their arms, the stresses in two of the principal arm bones are tensile right across the shaft, according to measurements reported by Sharon Swartz and her colleagues on page 270 of this issue[1]. By attaching strain gauges to the bones of captive gibbons and recording, by radiotelemetry, the strains during brachiation, they found that the humerus and ulna experience almost axial tensile loads. The radius, however, experiences bending moments because it is curved and is pulled on by the muscles that hold the fingers hooked over the branch.

A given force sets up much larger stresses in bones (or other long, slender structures) if it acts at even quite a small angle to the shaft than if it acts precisely axially. Gibbons can make do with remarkably slender arm bones because they load them axially: the humerus, for example, is 1.7 times as long as predicted for typical primates of the same body mass, but barely thicker than predicted[2].



Compare a gibbon of mass m and arms of length l, with a biped of the same mass and with legs also of length l. Suppose that the gibbon reaches out to a branch that is level with its shoulder and starts swinging. In the initial downswing it loses height l and gains speed v. The lost potential energy is converted to kinetic energy, so $v = \sqrt{2gl}$. The gibbon reaches this maximum speed in each swing, but its mean speed over a complete cycle of brachiation depends on the angle of swing, α (see figure). For $\alpha = 90°$, the mean speed is $0.5\sqrt{gl}$ (calculated as in ref. 3); for small values of α, it approaches $1.4\sqrt{gl}$. The force transmitted by the arm at the bottom of each swing is the weight plus the centripetal force, $mg + (mv^2/l) = 3mg$. If the arm is kept straight, the load on the bones is axial.

Our theoretical biped could maintain the axial load on its bones by keeping the supporting leg straight, as walking people do, but the axial load would be compressive rather than tensile as in the gibbon arm. Long leg bones could not be very slender or they would buckle under this load. Also, a biped using a straight-legged walk could not travel faster than $\sqrt{gl}$ because higher speeds would require downward accelerations greater than gravitational g (ref. 4). To travel faster, the biped would have to run, bending the legs at the knee and exposing the bones to bending moments. The peak force on a human runner's foot is about $2.8\,mg$, almost the same multiple of body weight as on the hand of our theoretical gibbon, but our theoretical biped would need leg bones thicker than the gibbon's arm bones to withstand the bending moments.

What would happen if the gibbon and the biped evolved longer limbs? By the argument already presented, the gibbon's speed would increase in proportion to the square root of its arm length. Similarly, the biped would increase speed in proportion to the square root of its leg length if it maintained dynamic similarity of gait[5]. In both cases the forces on the limb would remain unchanged, but the bending moments would increase in the biped in proportion to leg length. The longer-armed gibbon has no need for its bones to be thicker but the longer-legged biped does need thicker bones.

Gibbons are not limited by the speed they can gain in the first swing, but can accelerate by using leg movements like a child 'pumping' a swing[6]. They could accelerate faster by bending and extending the supporting arm instead of the legs, at appropriate stages of the swing, but that would result in bending moments. The penalty for relying on slender tensile arms is poor acceleration.

Finally, the really bad news, gibbon bones often get broken[7]. ☐

EVOLUTION

Parasitological teeth for evolutionary problems

Paul H Harvey

EVOLUTIONARY biologists have much to gain from a closer association with parasitologists It is not just that parasites have been overlooked for too long as a selective force, and that a considered assessment may show them to be at least partly responsible for a few of the problems that Darwin left us — sex, sexual selection and sociality have received attention recently There is more to it than that A parasitological perspective may shed light on evolutionary problems that do not necessarily involve one species parasitizing another Graham Bell and Austin Burt's assessment of the evolutionary significance of B chromosomes, which was presented at a recent symposium on evolutionary approaches to parasitism*, nicely illustrates the point

B chromosomes are distinguished from A chromosomes both by differing in number between individuals of the same species and by being unnecessary for the survival or reproduction of the individuals that possess them They are extremely common, probably being present in 10–15 per cent of eukaryotic species, and are typically small Often they are extensively heterochromatized — pointing to genetic inertness Even though they may have originated from the autosomes or sex chromosomes of the lineage in which they are found, B chromosomes have clearly evolved properties of their own In several plant species, B chromosomes are lost from the root tissue but retained in the aerial parts And, in the growing shoots, they may be lost from tissues that will become nonreproductive, yet increase in numbers in tissue that will give rise to the germ line Similarly, whereas small univalent chromosomes and chromosome fragments tend to be lost during meiosis, B chromosomes may actually accumulate In organisms ranging from grasshoppers to rye grass, the B chromosomes move preferentially during meiosis to those daughter nuclei that will give rise to germ cells rather than polar bodies or nongenerative nuclei

Given this accumulation of B chromosomes in the germ cells, why do their numbers not increase from generation to generation? The answer seems to be that they reduce the darwinian fitness of their hosts Cells with more DNA take longer to divide, and at least one study demonstrates that B chromatin adds about twice the amount of time to a typical cell division compared with a similar mass of A chromatin Morphological comparisons from a number of plant and animal species indicate that individuals with more B chromosomes usually exhibit delayed development, which is often accompanied by reduced vigour and fertility In other words, B chromosomes bear all the hallmarks of successful parasites

According to R N Jones and H Rees (*B-Chromosomes*, Academic, London, 1982), the parasite theory for B chromosomes was suggested as long ago as 1945 by G Ostergren Since then it has largely gone out of fashion and B chromosomes have been viewed as either of neutral selective value, or as being advantageous to the individuals or species that bear them The parasite theory, however, does in fact seem successfully to accommodate recent observations What is more, the theory makes fairly straightforward predictions that remain to be tested For example, if B chromosomes are disadvantageous to their hosts, they should be lost from clonal lines and asexual species In Bell and Burt's terminology, B chromosomes constitute not merely a disease, but a sexually transmitted disease

The parasitological perspective on B chromosome evolution may lead to the reinterpretation of other observations For example, there seems to be additive genetic variance for the presence and number of B chromosomes, which might be interpreted as differential resistance by particular sets of autosomes to invasion by B chromosomes If that is so, the 'Red Queen' theory for the evolution of recombination (selection in response to ever-changing environmental challenges) might be invoked that is, we might expect individuals possessing B chromosomes to increase recombination among the autosomes, so that new genetic variants that are resistant to B chromosomes would be more likely to arise At the same time, we should expect successful B chromosomes to reduce the rates of recombination in their hosts

So far, the evidence bearing on these questions, as reviewed by Bell and Burt, shows no consistent patterns Working out concise predictions, suitable comparative tests and experimental protocols are tasks for the future But to ask whether the work will be carried out by parasitologists or evolutionary biologists depends on an outmoded distinction between scientists with identical perspectives ☐

DAEDALUS

Earth, wind and fire

SOME time ago the 'hydrogen economy' was proposed as a way of avoiding pollution Hydrogen would be made in bulk by the nuclear-powered electrolysis of water or, perhaps, by the chemical transformation of oil A universal fuel, it would burn cleanly to harmless water

This green dream soon faded into well deserved oblivion Nuclear power has its own potential for environmental disaster, and the generation of hydrogen from oil liberates as much greenhouse-inducing carbon dioxide as simply burning the oil in the usual way But Daedalus is now reviving the idea His plan is to turn the oil into hydrogen while it is still in the ground

The modern steam-reforming catalytic hydrogen process would be hard to employ on crude oil *in situ* Steam, heat and catalyst would all have to be fed continuously down the borehole But Daedalus recalls the old partial-oxidation process which burnt crude oil in a limited supply of pressurized oxygen with a little steam in it, giving mainly hydrogen and carbon dioxide No catalyst or added heat was needed So Daedalus plans to pump oxygen and water down a test oil well, ignite the mixture electrically at the bottom and collect the resulting hydrogen from a central exit pipe

Deep in the Earth, the process will run under great hydrostatic pressure Carbon dioxide and undesirable by-products will dissolve in excess condensed water, and the pressurized solution will soak back into the porous oil-bearing rock as fast as the oil flows out of it So the nasties will stay underground, only hydrogen will be volatile enough to escape to the surface

Geohydrogen would be tricky to distribute Overland, it could travel through the pipelines that now take oil and gas But as bulk sea-freight it would be troublesome Daedalus proposes to tow it round the world in captive balloons

A small tug could easily tow a big balloon full of hydrogen Even better, the balloon might tow the tug The wind direction often varies markedly with height, and by winching the balloon up to the right altitude, the tug could be pulled in any chosen direction — a wonderful advance on the traditional sailing ship Once discharged at its destination, the deflated balloon could be stowed on board the tug for the journey back to the oil field

As a major fuel, hydrogen could be piped around like domestic or industrial gas It could provide heat, power and clean water simultaneously and economically, wherever they are needed, ideally by means of a fuel cell All potential pollutants would be left behind in the oil fields Future geologists, prospecting for what remains of the oil, may be puzzled to strike dirty soda water

David Jones

Mechanism of solid-state fusion

SIR—Experiments by Derjaguin *et al*[1,2] indicating that MeV neutrons were emitted during the destruction of heavy ice or monocrystals of LiD went almost unnoticed, whereas recent claims of 'cold fusion'[3,4] have attracted worldwide attention, ranging from highly enthusiastic confirmations to equally sceptical rejections Here we wish to present some relevant considerations of mechanisms which could enhance nuclear interactions in the solid state

A body of experimental evidence[5,6] suggests that hydrogen resides in transition metals as a simple 'lattice gas' Although the rate for nuclear fusion of d + d in the lattice may be increased over the 'free' rate because of screening of the repulsive Coulomb potential by lattice electrons, the enhancement cannot be large enough[7] to explain the claims of refs 3 and 4 Likewise, single-neutron tunnelling at low energies (the Oppenheimer–Philips mechanism[8]) will not do the job, and an excited resonance state in ^{4}He (ref 9), because under these conditions the tunnelling time is much longer than the lifetime of the resonant state

Any enhancement of the fusion rate must then be 'chemical' in origin — the potential barrier between deuterons may change shape substantially, or deuterons may gain some unusual thermal activation

An increase in the density and effective mass of lattice electrons can cause a decrease of the shielding radius and a corresponding increase in barrier penetrability In addition, the combined effects of a redistribution of electrons and lattice deformation may produce a local minimum in the potential barrier Under the right conditions, a quasi-stationary complex can form, and an effect known as resonance transparency may appear[10] If such a complex has a vibrational frequency with an energy ~ 0 1 eV, the effective collision frequency of deuterons can be greater by as much as a factor of 10^9 over the simple 'lattice gas' value

A considerable increase in the fusion rate would also come about if a single deuteron were able to acquire ~ 10 keV of energy In a lattice in equilibrium such an energy transfer would not occur, but perhaps during the destruction of a lattice there might be significant localization of the destruction energy, which could be transferred to absorbed deuterons A macroscopic version of this effect is found in the electrostatic acceleration of deuterium ions in cracks, which, as noted by Cohen and Davies in their recent News and Views article[11], is apparently responsible for the appearance of neutrons during the shock destruction of D_2O and LiD (refs 1 and 2)

This is then a problem in piconuclear (pressure-induced) reactions rather than in thermonuclear reactions Common features may apply in the various experiments high overvoltages and D compression in ref 3, cold fusion in natural geophysical conditions in ref 4, and high static pressures and shears in refs 1 and 2

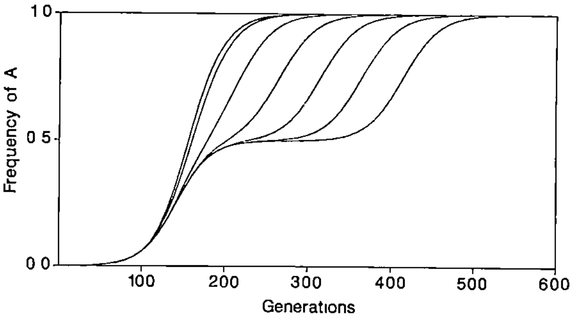
Sex in diploids

SIR—Kirkpatrick and Jenkins[1] suggest that the origin and maintenance of sex in diploids is related to the advantage conferred by genetic segregation They contend that the segregation advantage gained by facilitating the fixation of advantageous mutations more than compensates for the twofold reproduction advantage of asexual reproduction We point out here that the segregation advantage they discuss is present even when only a very small proportion of individuals in a population reproduce sexually

To illustrate this, we have compared the pattern of increase in the frequency of a favourable allele in a population with only sexual reproduction to that in populations where there is a mixture of sexual and asexual reproduction[2] As an example, the figure shows the change in allelic frequency of advantageous mutation A when there is a 10 per cent selective difference between homozygotes and the heterozygotes are exactly intermediate in fitness Note first that the initial increase from 0 001 to nearly 0 5 occurs essentially at the same rate for all levels of sexual reproduction Furthermore, even if there is only a very small amount of sexual reproduction, the continued increase of the advantageous allele from 0 5 to fixation is nearly as fast as that in a completely sexually reproducing population



The change in frequency of advantageous mutation A for different amounts of sexual reproduction For the curve on the far right the proportion of sexual reproduction is 10^{-7} (1 in 10 million individuals reproduce sexually) Successive curves to the left are for increasing amounts of sexual reproduction (10^{-6}, 10^{-5}, 10^{-1}) The curve for 10 per cent sexual reproduction is indistinguishable from 100 per cent sexual reproduction

Kirkpatrick and Jenkins show that there is a plateau at a frequency of 0 5 for the heterozygous asexual population while it is waiting for the occurrence of a second mutation We observe a temporary plateau at an allelic frequency of 0 5 only when the proportion of sexual reproduction is about 10^{-6} or smaller This plateau, which is generally very short and in the most extreme case in the figure only doubles the time to fixation of the favourable mutant, occurs because the population consists of nearly 100% heterozygotes at the beginning of this period and is waiting for segregation to produce AA homozygotes (which it will at a rate about ¼ times the rate of sexual reproduction) We also find that the relative duration of this plateau is even shorter when the selective difference between the homozygotes is reduced

A number of species have a small (but not zero) amount of sexual reproduction[2,3] Perhaps this is a way in which a species can have both the segregation advantage discussed by Kirkpatrick and Jenkins and the twofold advantage of asexuality many others have noted In other words, we see why some sexual reproduction should be favoured over complete asexual reproduction because of the segregation advantage, but it is not clear why a lot of sexual reproduction should be favoured over a little[4]

SIR—I believe that the mechanism proposed by Kirkpatrick and Jenkins[1] is unlikely to offer a sufficient explanation for the maintenance of diploid sex

Of critical importance in assessing the potential role of the segregation advantage[1] in maintaining diploid sex is the fact that the gradual accumulation of beneficial homozygous loci by a sexual population can only lead to gradual increases in its relative fitness Hence, a significant time period (Kirkpatrick and Jenkins provide an estimate of ~10^6 generations) would be required before the level of homozygosity in a sexual population could counterbalance the supposedly inherent twofold fitness advantage of asexual reproduction But throughout these many generations the asexual population would enjoy a large, slowly diminishing selective advantage, which should result in the competitive elimination of the sexual population long before its fitness approaches that of the asexual population In addition, competition with a more fit asexual population would lead to a continuous reduction in the size of the sexual population, slowing its relative rate of production of new beneficial mutant alleles, and further reducing its competitive prospects Even if the sexual population eliminated the asexual population, new asexual mutants, starting with the same genetic complement as the sexual population, would again enjoy a selective advantage for, say, ~10^6 generations In the absence of any advantage to sex other than an initially higher rate of fixing homozygous loci, the repeated appearance of such mutants would keep a sexual population at a constant disadvantage

The segregation advantage cannot explain the evolution of sex or its maintenance in haploid forms[1] However, the existence of sex in species with predominantly haploid life cycles implies a selective advantage sufficient to overcome any costs associated with meiosis Surely, parsimony supports a single explanation for the maintenance of sex in both diploid and haploid species rather than hypotheses exclusive to either group

KIRKPATRICK AND JENKINS REPLY—We showed[1] that the process of genetic segregation can generate an evolutionary advantage to sexual reproduction that may help explain its prevalence over asexual reproduction Hedrick and Whittam point out that the segregation advantage we identified will be almost as effective in a population in which most individuals are asexual and only a small fraction are sexual Such a facultatively sexual population would have the best of both worlds most of the segregation advantage from sexual reproduction and most of the twofold reproductive advantage from asexual reproduction Species of this type, however, are virtually unknown among the animals[5], and so this may not be an evolutionary option (We do not consider automixis (selfing) here because the ubiquitous deleterious effects of inbreeding[6] probably select against it in most populations) We have extended Hedrick and Whittam's observation by considering the more common (though still rare) situation of cyclic parthenogenesis, in which the population undergoes a number of strictly asexual generations followed by a single generation of sexual reproduction[5] The results are similar to Hedrick and Whittam's an occasional generation of sexual reproduction is sufficient to give most of the segregation advantage and still retain most of the twofold reproductive advantage of asexuality

Why then are facultative and cyclic parthenogenesis uncommon? We have two possible explanations First, the segregation effect we identified is only one of the evoluntionary advantages to sex Others, such as effects from recombination[4,5,7], may work in conjunction with the segregation effect to give purely sexual reproduction an overall advantage Second, constraints may preclude facultative and cyclic parthenogensis as evolutionary options for many taxa[4,5] Pure apomictic parthenogensis has appeared dozens of times among the animals, but facultative and cyclic apomictic reproduction have arisen perhaps only half a dozen times[5] Thus, for most taxa the evolutionary possibilities may be purely sexual or purely asexual reproduction In this case, the benefits to sex from the effects of segregation and recombination may be sufficient to maintain sexual reproduction

Dunbrack reiterates two points made in our paper that there can be a substantial time lag before the segregation advantage offsets the twofold reproductive advantage of asexual reproduction, and that the segregation advantage will be greatly weakened when much or all of the genome is selected in a haploid state for a substantial part of the life cycle Dunbrack feels these points are fatal to our hypothesis We disagree based on the arguments presented in our paper, and re-emphasize that there need not be only one evolutionary advantage to sex — the segregation effect can be augmented by others

More on cold fusion

SIR—Processes involving cosmic-ray muons have been proposed[1–3] to explain the small rate of fusion neutrons observed[4] in the cold-fusion experiments Although fusion neutrons have not been observed in electrochemical cells placed in muon beams[5,6], the flux from the control experiment has not been measured Any cold-fusion neutrons of amuonic origin would remain unaffected by the muon beam These muon experiments therefore demonstrate negative results for cold fusion — both muonic and amuonic in deuterium-charged metals The muon experiments establish that the deuteron concentration in the samples does not reach abnormally high densities because the muons are lost to the more electropositive host-metal ions as expected for normal ratios of deuterons to metal-ions (up to two) Under conditions of high-density non-equilibrium deuteron packing as predicted by some of the cold-fusion experiments[7] and theories, the muon kinetics are not known, but loss to the host metal should be hindered, as it is known to be sometimes delayed[8] even in ordinary compounds because of intermediate molecular states

Known cosmic-ray muon fluxes[9,10], their stopping rates[11], and established muon-catalysed-fusion parameters[12,13] indicate that exposure of a large enough volume of liquid deuterium (about 1 litre) to cosmic-ray muons should also yield a low-level neutron count of about 10^{-2} s^{-1} There is a possibility of using these fusions for fissile-fuel breeding Although the rate would be extremely slow, the muons would be free and the muon-production cost factor could be dropped from the efficiency calculations for muon-catalysed fusion

High-latitude ozone loss outside the Antarctic ozone hole

M. H. Proffitt[*†], **D. W. Fahey**[*], **K. K. Kelly**[*] **& A. F. Tuck**[*]

[*] NOAA Aeronomy Laboratory, 325 Broadway, Boulder, Colorado 80303, USA
[†] CIRES, University of Colorado, Boulder, Colorado 80309, USA

Data taken during the 1987 Antarctic Airborne Ozone Experiment based in Punta Arenas, Chile, are used to show that from mid-August until the end of the mission in late September there was a high-latitude ozone loss outside the Antarctic ozone hole. Therefore, not only is the geographic extent of the ozone loss larger than that generally identified as chemically perturbed, but ozone is lost earlier in the year than previously reported. These results, when compared with long-term temporal trends of column ozone, indicate a possible anthropogenic component for this loss.

MEASUREMENTS from the past few years have shown that stratospheric ozone decreases substantially over Antarctica during September and October and that these decreases have intensified dramatically during the past decade. The intensification has been attributed to man's release of certain chlorine-containing compounds, primarily chlorofluorocarbons. The region of very high ozone decrease, usually referred to as the ozone hole, approximately covers the Antarctic continent, and is coincident with what is commonly called the polar vortex. Horizontally, the polar vortex is roughly defined by its perimeter, the polar night jet, a circumpolar wind belt in the stratosphere that seems to restrict exchange of air through the perimeter. The seasonal period of low ozone values is observed to terminate with the annual dissipation of the Antarctic vortex during the spring warming, at which time the air within the vortex is no longer restricted but allowed to mix freely with ozone-rich air from other latitudes. Transport towards the Equator and mixing of ozone-poor air with air at lower latitudes result in localized decreases of ozone[1]. The extent and intensity of these decreases are of global concern.

The seasonal decrease in ozone is large enough to provide an unequivocal signature of loss that is easily distinguished from natural short-term dynamical variability, and has been verified from the ground, aircraft, ballons and satellites. In this paper 'ozone loss' is used to identify a change in ozone due to chemical mechanisms (rather than dynamical processes) that is not predicted within standard gas-phase photochemistry models. We do not intend to imply the loss is necessarily due solely to chlorine. Measurements of total column ozone (total number of ozone molecules vertically above some area of the Earth) made from the ground and from a single station first identified ozone loss over Antarctica[2]. Satellite column measurements then verified that it was not just a local phenomenon[3]. Measurements obtained from balloons provided snapshots of the vertical distribution of ozone at a few Antarctic locations and presented striking accounts of large ozone decreases when comparing profiles from August with those from October[4,5]. But the changes observed were not simply a gradual deterioration of the ozone layer, but included a substantial day-to-day variability and frequent horizontal layering. This means that the region of decreased ozone is neither vertically nor horizontally homogeneous, and that quantification of the altitude-dependent decrease of ozone requires good temporal and geographic coverage. Although satellite measurements of total column ozone are frequently available, they cannot identify the altitude dependence of the ozone loss. *In situ* aircraft measurements can provide vertical profiles and extended horizontal coverage, but they are still insufficient to sample the entire geographic extent of the vortex frequently.

Here we present a different approach to estimating the ozone (O_3) loss inside and, more interestingly, outside the ozone hole—one that completely avoids the problems of sampling an inhomogeneous air mass. As standard gas-phase photochemistry is very slow in the region of this analysis (that is, during high-latitude winter in the lower stratosphere where O_3 has a photochemical replacement time of more than a year[6,7]), O_3 can be used effectively as a conservative tracer. The sum of the reactive nitrogen species (abbreviated as NO_y and including in that sum NO, NO_2, NO_3, HNO_3, N_2O_5 and $ClONO_2$) and nitrous oxide (N_2O) are also conserved in this environment. By combining *in situ* measurements of these tracers with empirically derived formulations that are supported by two-dimensional atmospheric models, minimum reference values for unperturbed O_3 can be estimated for any air parcel sampled. This reference value for O_3 can then be compared with the measured value, and the difference is a deviation from conservative behaviour that can be interpreted as a chemically induced change not within the standard gas-phase photochemistry. The formulations presented are first applied outside the region usually referred to as chemically perturbed. Then the analysis is used in a different manner, but this time both outside and inside. It is assumed for the analysis that there has been sufficient simultaneous sampling of the trace constituents NO_y, N_2O and O_3,

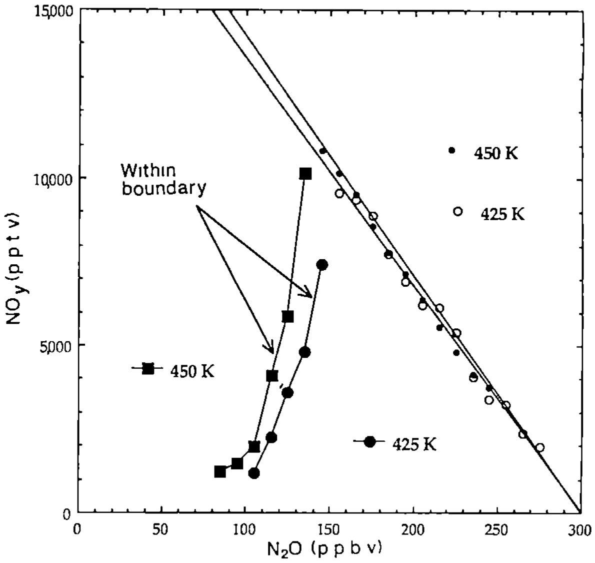

FIG 1 NO_y against N_2O from 1987 AAOE for the 425-K and 450-K flight levels and averaged for the seven flights where data are available over intervals of 1° latitude. Data taken within clouds were excluded to obtain only gas-phase NO_y. Linear least-squares fits to the data outside the boundary are shown for each flight level.

spatially and temporally, to determine reliable reference formulations.

To discuss accurately the morphology of the ozone hole, the concept of the boundary of the chemically perturbed region is used as introduced and developed by Proffitt *et al*[8] from data taken during the 1987 Antarctic Airborne Ozone Experiment (AAOE). The boundary, defined by a level of chlorine monoxide (ClO = 130 p.p.t.v. (parts per 10^{12} by volume)), effectively locates where this critical component in the catalytic destruction of O_3 by chlorine has a sharp poleward increase. It was found that there were also dramatic poleward decreases in NO_y and H_2O at this boundary, hence the basis for describing the interior region as chemically perturbed. We shall refine this description slightly by referring to this region as 'high chemically perturbed', and thereby not exclude a possible lesser degree of chemical perturbation outside the boundary. Proffitt *et al.* have shown that this boundary is slightly poleward of the peak wind speeds of the polar night jet and that it coincides with the latitude of the strong poleward decrease in total column O_3 as measured by satellite. In addition, the boundary locates the perimeter of the large isentropic temporal O_3 decrease (ozone hole) to within at least 1° of latitude (~111 km).

Danielsen and Houben[9] give heuristic arguments for wintertime diabatic cooling over Antarctica persisting into early spring, carrying ozone-rich mid-latitude air downward and poleward into the polar vortex. Proffitt *et al*[10] have presented supporting evidence from AAOE indicating a slow progression of diabatically cooling and descending lower statospheric air advectively spiralling poleward as it crosses the polar jet into the ozone hole. This view can be compared with that of Tuck[11], who also concludes that there is a significant mass flow through the vortex, but argues that it is the downward diabatic motion within and outside the vortex that is important. With either view, the region near and within the ozone hole is being slowly replenished with mid-latitude ozone-rich stratospheric air during the period of O_3 decrease through diabatic descent. If this is the case, temporal trends in measured O_3 will not indicate the total loss of O_3 in a particular parcel of air unless the time series begins before there is any loss and the measurements follow the descending parcel throughout the time interval of the trend[10]. This is a difficult, if not impossible, sampling requirement, even with precise knowledge of a parcel's descent path. Possible mixing of air parcels of dissimilar origin during or following the O_3 destruction process further complicates the sampling problem.

The analysis presented is based entirely on the *in situ* data taken during AAOE from the high-altitude ER-2 aircraft. During the mission the average latitude of the boundary was 66° S, but varied from 59° S to 71° S, its position responding to synoptic-scale meteorological forcing of the polar vortex. The data are generally restricted vertically to the two levels of 425 ± 10 K and 450 ± 10 K in potential temperature (corresponding to geometric altitudes ~17.5 km and 19 km respectively over Antarctica) and horizontally from 53° S to 72° S latitude at ~65° W longitude. The longitudinal coverage is quite restricted, extending only from the southern tip of South America to the region over or near the Antarctic Peninsula. Also, data were collected during the transit flights between Moffett Field, California (37° N) and Punta Arenas, Chile (53° S), where the twelve ER-2 Antarctic flights originated.

Lower limit for unperturbed ozone

The stratospheric source for NO_y is the very unreactive species N_2O. The primary destruction mechanism for N_2O is ultraviolet radiation at wavelengths ≤225 nm, has N_2 and $O(^1D)$ as principal products, and occurs primarily in the middle of the stratosphere above 30 km. A secondary loss occurs also in the middle stratosphere where NO is created in the reaction of $O(^1D)$ with N_2O, providing the primary source of NO_y. Plots of N_2O against NO_y outside the boundary show them to be linearly related (Fig. 1). These data are from the two flight levels of 425 K and 450 K of potential temperature and were analysed separately by averaging within 1°-latitude bins with respect to the boundary and over a one-month period. The data in Fig. 1 labelled as within the boundary (corresponding to $N_2O \leq 140$ p.p.b.v. (parts per 10^9 by volume)) are known to be from within the highly chemically perturbed region. Linear least-squares fits are shown for the data outside this region and it is apparent that the straight line that fits the data at the lower altitude (or potential temperature) also fits the data at the upper altitude rather well. The linear fit to all of the points in Fig. 1 outside the boundary is given by

$$[NO_y] = 20{,}800 - (69.8 \times [N_2O]) \qquad (1)$$

where the mixing ratio for NO_y is in p.p.t.v. and for N_2O is in p.p.b.v.[10,12,13] It is noteworthy that data taken during the flights from Punta Arenas to Moffett Field, where minimum values for N_2O of 210 p.p.b.v. were observed, also fall on the same straight line[10]. There are few further data available to verify the persistence of the linear relationship at other seasons, latitudes and altitudes, although the mid-latitude Southern Hemisphere balloon data taken by Galbally *et al*[14] up to 30 km have the same characteristic. This persistent linear relationship and lack of curvature results from a balance of photochemistry, transport

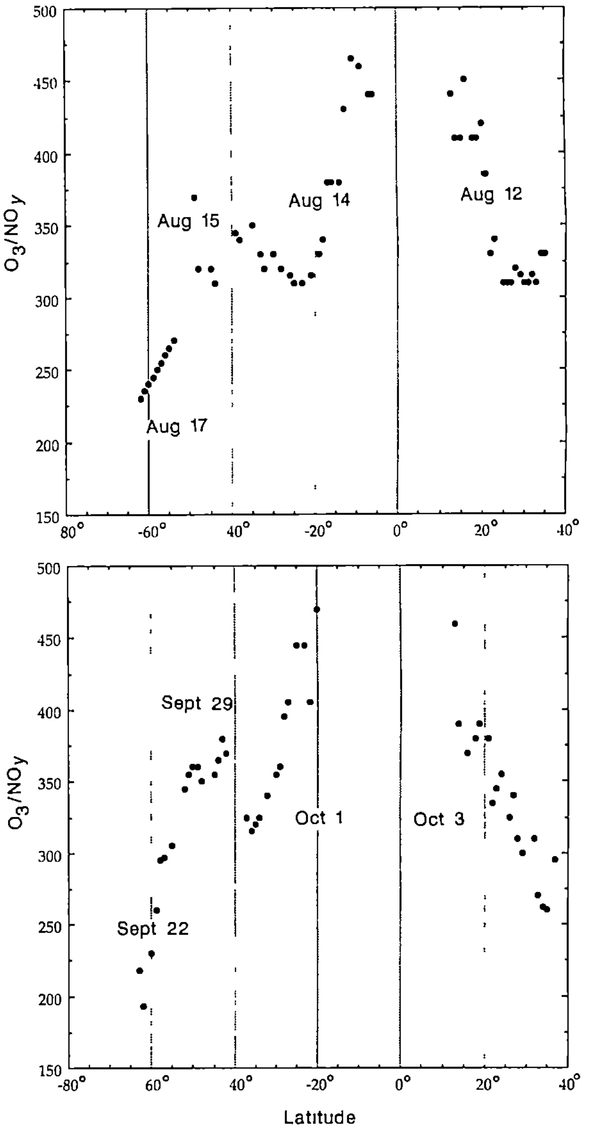

FIG. 2 O_3/NO_y latitude survey from *a*, 12 August to 17 August, 1987 and *b*, 22 September to 3 October, 1987.

and mixing. The N_2O intercept and slope are probably determined in the tropics where upper tropospheric and lower stratospheric air with N_2O of ~300 p.p.b.v. and NO_y <0.5 p.p.b.v. (intercept) rises into the tropical middle stratosphere where NO_y is produced from N_2O apparently with an average efficiency of ~7% (slope). Mixing, as the middle stratospheric air proceeds poleward, probably contributes to the observed small variability from linearity observed at high latitudes.

The ratio of O_3 to NO_y (O_3/NO_y) can now be used to bring O_3 into the analysis. Figure 2*a* is a plot of O_3/NO_y against latitude taken at the start of the mission and includes data taken in transit from Moffett Field to Punta Arenas. The ratio is >300 over a wide range in latitudes, but decreases at the most southerly latitudes. Figure 2*b* is a similar latitude survey including the last Antarctic flight and the transit flight data during the return to Moffett Field at the end of the mission. Still lower values at the southernmost latitudes and a few data points below 300 at about 35° N are the primary differences between the two surveys. Both figures are restricted to pressure altitudes from between 18 km and 21 km, and all data within the boundary are excluded. In both plots O_3/NO_y >300 at all latitudes north of ~55° S, except on the flight of 3 October over California, where a few values as low as 260 are found. Both surveys also show an enhanced ratio in the tropics where, at 20 km, stratospheric air is apparently encountered that had recent O_3 production without the equivalent NO_y production required for the usual ratio found at mid-latitudes. Other latitude surveys of ER-2 data taken during the Stratosphere Troposphere Exchange Project in January and February 1987 from 40° N to 30° S have been analysed (D. M. Murphy *et al.*, manuscript in preparation) and show a minimum for the ratio of 280 when restricting the data to potential temperatures >430 K. Also presented by Murphy *et al.* are two-dimensional model calculations[15,16] and satellite data[17] in the tropics and mid-latitudes covering pressures down to 7.5 mbar. Both the models and the data show that the O_3/NO_y ratio is >300 in the lower stratosphere and indicate either no vertical change or a slight decrease with altitude. Qualitatively these observations are consistent with the well-known mid-latitude mixing ratio maximum for O_3 and NO_y at 30–35 km with the maximum for NO_y a few kilometres higher than the O_3 maximum. These maxima correspond to N_2O values of 30–100 p.p.b.v., values much less than those measured outside the boundary and, as seen in Fig. 1, generally less than any data from AAOE.

From the observations made during ER-2 latitude surveys it is reasonable to assert that if NO_y and O_3 are given in identical units (such as p.p.b.v.) the inequality

$$[O_3]/[NO_y] \geq 270 \qquad (2)$$

is representative of late winter in the Southern Hemisphere north of the boundary. The data and model calculations indicate that a larger value of 300 for the minimum ratio could be justified. But there is no established record of simultaneous measurements of NO_y and O_3 covering all latitudes, seasons and altitudes of interest from which unequivocal formulations relating O_3 to NO_y could be derived. So the conservative approach taken here is appropriate, although it may underestimate the O_3 losses that have occurred.

Ozone losses

On 17 August between 54° S and 63° S (Fig. 2*a*), there was a significant difference between the expected O_3/NO_y ratio (inequality (2)) and its measured value. As NO_y was not perturbed and O_3/NO_y is less than our reference level of 270, an O_3 loss is indicated in that region. The value for O_3/NO_y of 230 at 63° S yields a 15% loss of O_3 outside the highly chemically perturbed region on 17 August. Data from the flight of 23 August also indicates a 15% loss outside the boundary, and the flights of 28 August and 22 September show a larger loss of 30%. But rather than giving flight-by-flight analysis, Fig. 3 shows averages for the period 23 August to 22 September to summarize the results and demonstrate that the O_3 losses are not isolated events found on certain flights, but were prevalent throughout the period and clearly seen in the averages. This is achieved by referencing the flight-leg data for NO_y and O_3 relative to the boundary, and then averaging the O_3/NO_y ratio over bins of 1° latitude. Only data for which NO_y is believed not to be enhanced by particles (as indicated by simultaneous particle measurements) have been plotted. This averaging procedure is done independently for both of the flight levels. The vertical bars represent the sample standard deviation and indicate how flight-by-flight variability affects the results.

The abrupt increase south of the boundary is due to the high degree of denitrification within the highly chemically perturbed region[13] and provides little information on the O_3 loss. We deal below with this region in a different way. However, outside the boundary where the NO_y is known to be unperturbed relative to N_2O, there are depressed ratios even below 200 near the boundary. These low ratios correspond to an average minimum O_3 loss of 15–30% in the first 5° of latitude outside the highly chemically perturbed region at these levels. It should be noted that the averaging over the one-month period is in a region where diabatic descent is believed to be taking place. An important feature in Fig. 3 is that outside the boundary the ratios at the 450-K level are ~20% higher than those at the 425-K level. This is not what would be expected from the model calculations and satellite data mentioned above, which show either no change in O_3/NO_y with altitude or a decrease. The implication is that the lowest values seen near but outside the boundary could not have come simply from vertical descent in this region. Proffitt *et al.*[10] show that within the averaging procedure used for Fig. 1, <10% of the air outside the boundary had come recently from the highly chemically perturbed region. Thus, if these results are accepted (that is, ongoing diabatic descent and little outward mixing at these potential temperatures) along with inequality (2), the decrease in the O_3/NO_y ratio, seen as the boundary is approached from the north, cannot be due to transport or mixing of air vertically nor horizontally, and therefore must be caused by some chemical mechanism operating at these levels outside the highly chemically perturbed region.

The isentropic temporal changes in O_3 outside the boundary

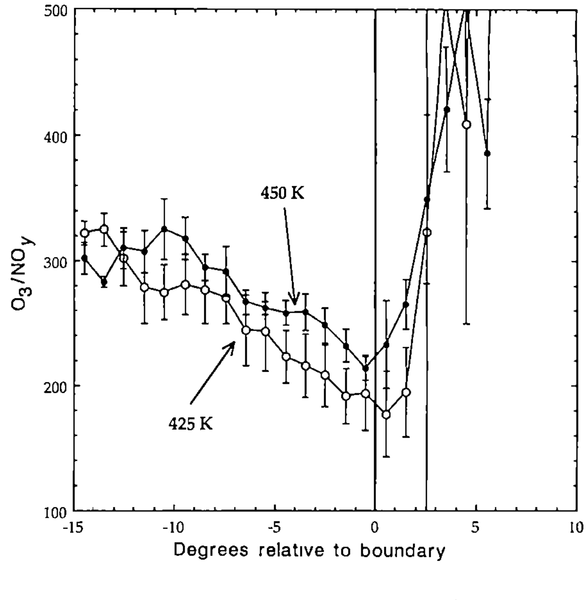

FIG. 3 O_3/NO_y against latitude relative to the boundary (heavy vertical line) for the 425-K and 450-K flight levels and averaged for the seven flights where data are available over intervals of 1° latitude. Data taken within clouds were excluded to obtain only gas-phase NO_y. Sample standard deviations are given as vertical bars.

during this one-month period are small in comparison with those inside, and in general are not significantly different from zero[18] As discussed in the introduction, losses of O_3 in a parcel of air undergoing diabatic descent will not be represented accurately by a temporal trend calculated at a constant potential temperature, because the losses will be masked by the usual vertical gradient in O_3 Therefore the lack of a significant isentropic temporal trend outside the boundary in no way indicates that no loss of O_3 is occurring there

To extend our analysis into the ozone hole and provide a check for consistency between two methods, equation (1) and inequality (2) are now combined into an inequality relating unperturbed O_3 directly to N_2O If O_3 and N_2O are both in ppbv

$$[O_3] \geqslant 5616 - (18\ 85 \times [N_2O]) \qquad (3)$$

provides a minimum value for unperturbed O_3 First note that this formula is based on measured data and may reflect systematic errors in the measurements In this regard, the O_3 measurement used here was generally within 2% of an independent measurement of O_3 made simultaneously on the ER-2[19,20] There was no independent check of the NO_y measurements except as they related to the O_3 data over a long history of more than 50 ER-2 flights, but they are reported to be accurate to within ±20% and repeatable (precise) to within at least 0 1 ppbv[13] The values used for N_2O are from the ATLAS instrument[21 22] and include a recent recalibration of the data that was not included in earlier papers[8 10-13 21,22] The reported accuracy of the N_2O measurements is ±10%

There is more uncertainty in applying inequality (3) inside the boundary where $N_2O < 140$ ppbv (see Fig 1), stemming from our lack of information to support equation (1) and inequality (2) at these more southerly latitudes Outside the boundary, equation (1) was used to test where NO_y was perturbed, then inequality (2) was used to predict O_3 By extending the application of inequality (3) to 72° S with its lower values for N_2O it is assumed that equation (1) remains linear and inequality (2) is still representative of O_3/NO_y The use of equation (1) at lower values of N_2O is supported by noting that the linear relationship between NO_y and N_2O is predicted to persist at mid-latitudes to at least 14 ppbv of NO_y in both a one-dimensional radiative convective photochemical model[23] and a two-dimensional model[16] Furthermore, the model calculations discussed earlier indicate that inequality (2) is satisfied at flight altitudes throughout our latitude range Therefore all information available supports inequality (3) for these low values of N_2O Implicit in the above discussion is that the formulations do have limits of applicability, the most obvious one being that they do not apply at altitudes above the maximum stratospheric mixing ratios for O_3 For at such altitudes, N_2O and O_3 are both decreasing with altitude but inequality (3) implies that as N_2O decreases, O_3 increases With this reservation a lower-limit estimate for unperturbed O_3 both outside and with increased reservation inside the boundary can now be calculated Figure 4*a*, *b* shows measured O_3 against latitude with respect to the boundary where O_3 is averaged over all ten flights from 23 August to 22 September at both flight levels Otherwise data are treated as in Fig 3 for O_3/NO_y Also plotted is the corresponding minimum value of unperturbed O_3 calculated from inequality (3) Figure 4*c* shows the O_3 loss with respect to the boundary, calculated as the percentage decrease in O_3 and based on Fig 4*a*, *b* The loss outside the boundary is typically 20-25% at 425 K for the first 5° with a maximum value indicated of ~30% From Fig 3 we obtained a maximum value of 30% O_3 loss outside the boundary, which is virtually identical to the loss shown in Fig 4*c*, although the analysis of Fig 3 includes only seven of the ten flights included in Fig 4 This difference in number of flights is because particle-free NO_y data are available only from seven flights Both analyses indicate that the loss is greater at the lower level, which is consistent with diabatic

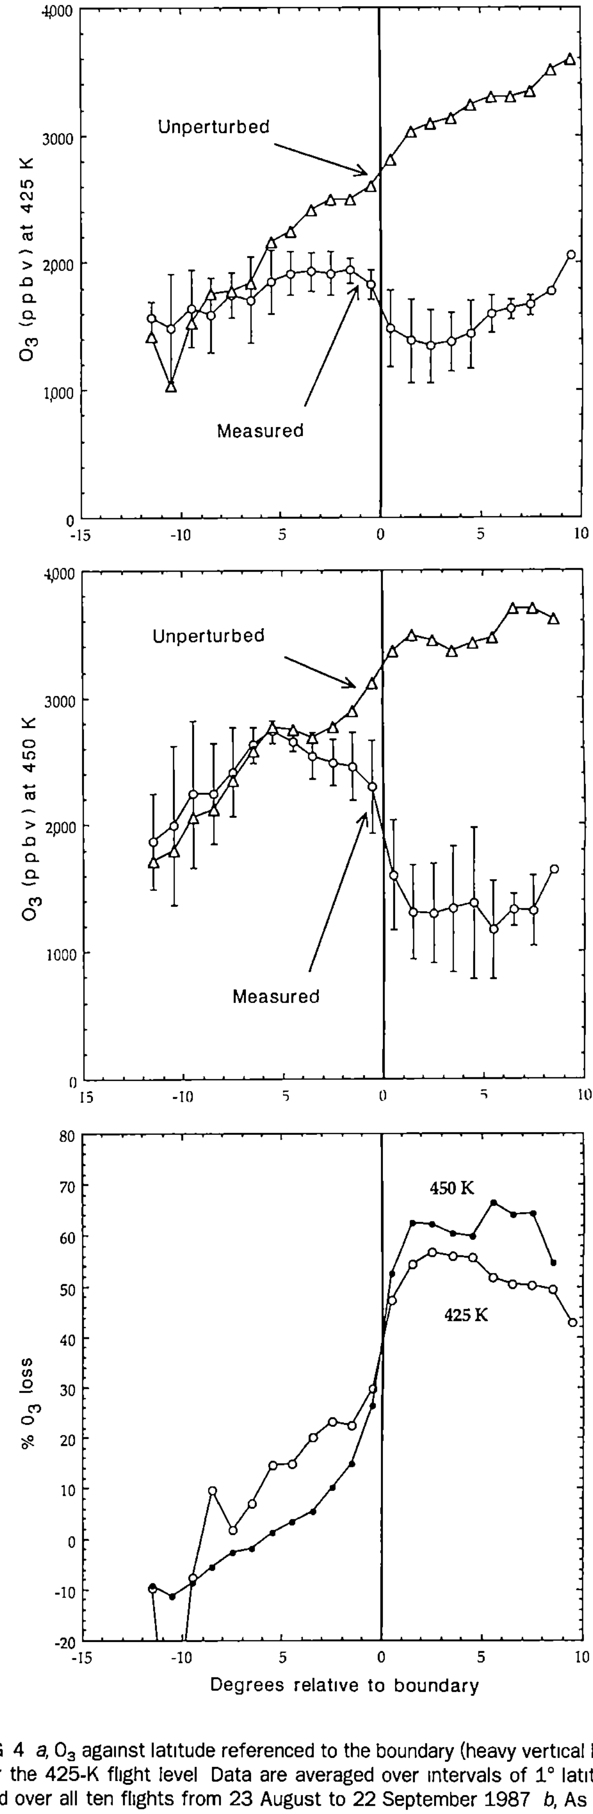

FIG 4 *a*, O_3 against latitude referenced to the boundary (heavy vertical line) for the 425-K flight level Data are averaged over intervals of 1° latitude and over all ten flights from 23 August to 22 September 1987 *b*, As in *a* except at 450-K flight level *c*, Average percent O_3 loss over 30 days derived from *a* and *b* descent and a simultaneous chemical loss of O_3

This analysis can also be applied to individual flights rather than averages of flights For example, from data taken on 23 August, the first day that a flight clearly penetrated the boundary, we calculate a 40% loss in O_3 inside the boundary On the last mission flight date, 22 September, still two weeks before the minimum column O_3 was measured in 1987 (ref 24), there was a 70-80% loss within the boundary in the layer between 17 5 km and 19 km This is substantially more than the 53% isentropic temporal decrease observed in the same region from 23 August to 22 September[18]

Discussion and conclusions

Since the ozone hole was first identified in 1985 it has been considered to be a recurring springtime event with a nearly monotonic increase of intensity over its history of ~10-15 years[25] Here we have presented strong evidence of significant O_3 loss occurring as early as mid-August both inside and outside the highly chemically perturbed region, and that this loss is chemical in origin rather than a result of atmospheric dynamics Although the mechanism for the chemical loss outside the boundary cannot be inferred from this approach, there is evidence of a temporal column O_3 decrease over the past decade in this region, therefore indicating that the chemical loss that we report has an anthropogenic component In particular, ref 26 shows, by comparing satellite data from 1979-80 with 1986-87, a nine-year temporal decrease from 6% to 18% in column O_3 between 60° S and 66° S during August and September, a region near, but on the average outside, the boundary during AAOE In ref 27 the data were analysed with a linear fit of the yearly data, starting with 1978 and ending with 1988 This analysis produced virtually identical trends from 60° S to 66° S from mid-August through September Both studies also show a long-term temporal decrease of more than 10%, poleward of 66° S during August These analyses present a consistent picture of mid-August O_3 decreases, both inside and outside the vortex, that have intensified during the past ten years The results we have presented co-locate a region of chemical O_3 loss with these long-term temporal decreases in O_3, suggesting that at least part of the loss has an anthropogenic origin

The cause of the O_3 loss outside the boundary, where the measured ClO is only 5-10% of the level measured inside the boundary, is not known, and more experimental investigation is warranted But it has been suggested by Tuck[11] that O_3 losses may occur near the boundary and outside the highly chemically perturbed region during June, July and August as long as there is sunlight Such losses would be due to reactive chlorine, as is the case within the ozone hole itself Support for this conclusion comes from photochemical model studies made along isentropic trajectories outside the boundary[28] These studies point out that the discrepancy between observed and measured values of ClO and NO indicates significantly perturbed photochemistry in this region without substantial denitrification In sunlight the formation of polar stratospheric clouds (PSCs) outside the boundary can perturb chlorine and nitrogen chemistry, initiating catalytic destruction cycles Observed temperatures are above the frost point on average, but low enough for PSCs to form that contain nitric acid, a component of NO_y[13,29] The NO_y measurements indicate that PSC formation does not generally lead to denitrification The maximum frequency of PSC formation over the continent and inside the vortex occur to the east of the ER-2 flight tracks over the Weddell Sea[30], downwind from the ER-2 flight track The perturbed levels of reactive chlorine initiated by the PSCs cannot be long-lived because of the lack of denitrification In sunlight, nitric acid will gradually photolyse to produce NO_2, and this will reduce ClO levels to near unperturbed values With such intermittent chemical perturbations, this region may contain sufficient recurrent enhancements in ClO to destroy O_3 to the extent indicated in our analysis

Obtaining values for unperturbed O_3 in the Antarctic from other species must carry with it some uncertainty, but the analysis presented here has been conservative In particular, if the value of 300 had been chosen for O_3/NO_y as is indicated by the Southern Hemisphere data, the analysis would have produced somewhat larger O_3 losses The negative O_3 loss 10-15° outside the boundary (Figs 3 and 4c) shows that the choice of 270 for the ratio is conservative Nevertheless, the method is more reliable than the simple 'before and after' comparisons of O_3 profiles which we strongly caution against when analysing losses of O_3 at high latitudes unless the losses are very large, as within the Antarctic ozone hole

We have analysed winter-time high-latitude O_3 changes in a region where O_3 is considered under dynamical control and standard gas-phase photochemistry is extremely slow We have estimated a reference state for O_3 in this region from other conserved trace species and compared this with measured values to determine a minimum loss in ozone In this context we can summarize the important conclusions as follows (1) There is a substantial O_3 loss by mid-August both inside and outside the highly chemically perturbed region, (2) For the first 5° outside the boundary, the average O_3 loss from 23 August to 22 September was at least 15-30% at 17 5 km and 4-25% at 19 km, (3) The O_3 loss found outside the boundary is chemical in origin and did not occur within the highly chemically perturbed region An anthropogenic component cannot be ruled out, (4) For the first 5° inside the boundary and in the layer between 17 5 and 19 km the air observed on 23 August had an O_3 loss of about 40% By 22 September there was an O_3 loss of at least 75%, much larger than the average isentropic temporal decrease of 53% from 23 August to 22 September

Reanalysis of an Old Order Amish pedigree, to include several new individuals and two changes in clinical status, markedly reduces the probability of linkage between bipolar affective disorder and the Harvey-*ras*-1 oncogene and insulin loci on chromosome 11 This linkage can be excluded using a large lateral extension of the original Amish pedigree

THE affective disorders are a common[1] and heterogeneous group of illnesses that are characterized by abnormalities of mood and cognition, as well as neurovegetative functions such as sleep, appetite and libido[2] Although the aetiology of these disorders is unknown, genetic factors appear to contribute to the development of both bipolar and unipolar depression[3] in many individuals whose families have multiple affected members[4,5] Attempts to delineate genetic loci for the various affective disorders have been hampered by the likely presence of genetic heterogeneity as well as nongenetic forms (phenocopies) of the disorder Several strategies have evolved to circumvent these problems Perhaps the most powerful of these has been the application of genetic linkage techniques to the study of populations that have developed from a restricted gene pool and hence have a more restricted array of alleles predisposing to affective disorder Egeland and co-workers[6] have identified several large pedigrees with a high incidence of affective disorder among the Old Order Amish located in southeastern Pennsylvania The Old Order Amish are a religious sect numbering ~15,000 who descend from some 30 pioneer couples and who have remained genetically isolated, thereby minimizing the introduction of multiple genes responsible for inherited disorders Amish families have large sibships and multiple living generations, making them ideal for genetic studies Alcohol and drug abuse, which often complicate psychiatric diagnoses, are rare among the Amish Bipolar affective disorder, however, occurs with a prevalence rate, characteristic symptom pattern and clinical course that are similar to those in the general North American population[7] The identification and characterization of these pedigrees[6,7] led to the initiation of early genetic linkage studies but no evidence for linkage between various polymorphic serum proteins or blood group antigen loci and affective disorder was found[8] More recently, using a molecular genetic approach, Egeland and colleagues reported evidence supporting the localization of a gene conferring a strong predisposition to bipolar affective disorder linked to two loci located on the short arm of chromosome 11, the Harvey-*ras*-1 oncogene locus (*HRAS*) and the insulin (*INS*) locus[9] Several studies in non-Amish families have excluded linkage between a single locus predisposing to affective disorder and these chromosome 11 markers[10,11]

The current set of analyses extend the original study by adding genotypic data obtained on several members not previously included, by incorporating new clinical data on several recent onsets of affective illness in previously unaffected members of the pedigree, and by extending the number of individuals under study with a large lateral extension of the original pedigree The addition of this new clinical and genetic data identified individuals in the core pedigree who were obligate recombinants with either marker when the diagnostic criteria used in the original study were applied The impact of these new data was to lower the overall lod score and hence weaken the evidence for linkage between an affective disorder locus on 11p15 and the *HRAS* and *INS* loci Also, the large lateral extension of pedigree 110 does not show linkage between these chromosome 11p15 markers and an affective disorder locus When combined with data from the original core pedigree, the hypothesis that a single affective disorder locus is linked to *HRAS* and *INS* in the entire pedigree could be excluded at a distance of 5 centimorgans (cM, a centimorgan is equivalent to 1% recombination between two loci and corresponds to $\sim 1\times 10^6$ base pairs of DNA) for *INS* and 10 cM for *HRAS* We conclude that the evidence for linkage between bipolar affective disorder and the *HRAS* and *INS* genes in the Old Order Amish is not as strong as was initially suggested

The extended and updated pedigree

The original pedigree 110, as previously reported, consisted of 81 subjects and includes the extended families of 6 ill probands 5 with bipolar affective disorder and 1 with schizoaffective disorder, circular type, as well as their first- and second-degree relatives (Fig 1) These patients were assessed by family study methods[12] They and their relatives were interviewed using the Schedule for Affective Disorder and Schizophrenia-Lifetime

Version (SADS-L)[13]. In addition, all hospital and clinic records were abstracted. The multiple SADS-L interviews and collated records were evaluated by a five-member psychiatric review board who were blind to patient identity and biological relationships. Most patients were diagnosed by the Board at two points in time and the reliability of diagnoses between assessors was high[12]. Nineteen of the 81 subjects in the original pedigree 110 were given diagnoses of major affective disorder according to Research Diagnostic Criteria (RDC)[14]. Fourteen had some form of bipolar disorder and five had unipolar depression. Five persons had minor depressive disorder by RDC and were treated as 'unaffected' in all the linkage analyses. One person who failed to meet RDC diagnostic criteria was diagnosed as having a 'bipolar-type' disorder by consensus of the psychiatric panel. Sixteen of 19 individuals with major affective disorder have been hospitalized at least once, yielding a total of 86 abstracted hospital records for diagnostic review. The availability of these multiple psychiatric evaluations contributed to the reliability of diagnoses in this study. The updated core pedigree includes data on two new unaffected individuals, new genotypes on ten unaffected members not included in the original study, and changes in diagnoses for two individuals owing to onset of illness subsequent to the initial linkage analysis.

The core pedigree of 81 subjects has been extended to include a small left extension closely related to the core pedigree through common great-grandparents (Fig. 1). This left extension consisting of six subjects (two with diagnoses of bipolar affective disorder) has been included in the linkage analysis of the updated core pedigree (Fig. 1 and Table 2). In addition, a large 31-member right extension (Fig. 1) has been studied; it contains eight individuals with a diagnosis of major affective disorder (four with bipolar disorder and four with major depressive disorder). Inspection of Fig. 1 reveals that individual C-4 connects this right extension to the core pedigree. This person and her spouse were psychiatrically well. Both, however, had uncles with RDC diagnoses of bipolar affective disorder (type I) by psychiatric board review. The decision to extend the pedigree through individual C-4, rather than C-3, was based on sibship structure and the segregation of the illness over four generations. Historical and geneological records of the upper generation (generation B, Fig. 1) of this right extension suggests the possibility that affective disorder in this extension may have been introduced by an Amish-Mennonite family whose surname is no longer found among members of the Amish community (Fig. 1). Consequently, for the linkage analysis, the right extension was analysed both separately and combined with the updated core pedigree (Table 2).

As part of the Amish Study, each subject (for whom immortalized cell lines have been established) is visited annually by a staff member. Field work is carried out by staff members who are blind to the genotypes of all subjects. As a result of this longitudinal evaluation, it has been noted that since the initial analysis of the data, the clinical status of two individuals (III-21, IV-20) (Fig. 1) has changed from unaffected to affected.

Defining a diagnostic hierarchy

Relatives of individuals with bipolar affective disorder have been found to have a variety of affective and nonaffective psychiatric syndromes[15]. These include individuals with

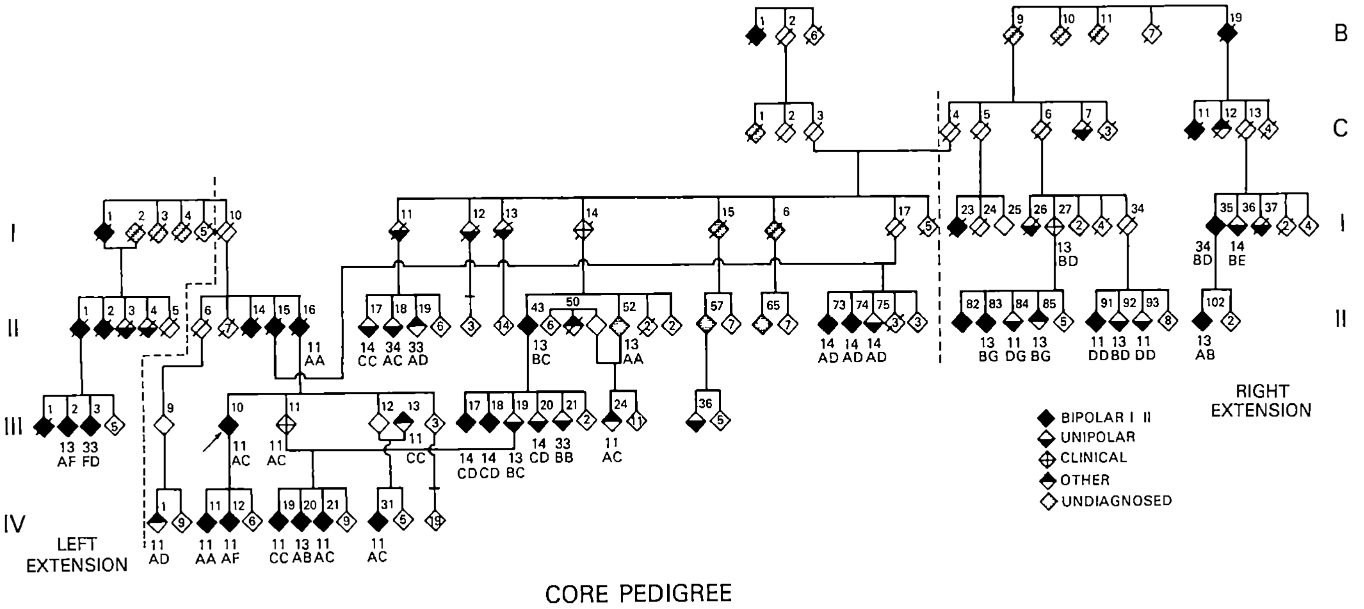

FIG. 1 Pedigree 110 and its extensions. The structure of the 120 member family (pedigree 110) used in this study is shown. The dotted lines distinguish the left and right extensions from the core pedigree. Sex and birth order have been disguised to protect anonymity. Genotypes are not included for the unaffected members to protect those for whom a genetic vulnerability might be indicated. Of those with diagnoses designated 'other', subject III-24 has schizoaffective illness, the rest have minor depressions. Genotypes are designated with numbers, 1–4, for *HRAS*, and with letters, A–G, for *INS*. In several members of the right extension, one laboratory (NIMH) identified another *INS* allele, H, which is 2.4 kb in size, and, therefore, difficult to distinguish from the D allele. In the analyses reported here, the H allele was scored as D, because of the difficulty in resolving the two alleles. The linkage analyses also were carried out using the H allele resulting in somewhat more negative lod scores, but changing neither the basic conclusions nor the size of the exclusionary range (data not shown). Genotypes were determined independently in two laboratories, NIMH and St Louis. In the initial analysis several discrepancies in genotypings were obtained and were resolved by reanalysis in both laboratories except for one individual (III-20), and a new DNA sample will be needed to resolve this discrepancy. The St Louis genotypings were carried out as previously described[9]. In the NIMH protocol, genomic DNA was digested with the appropriate endonuclease (*SstI* for *HRAS* or *PvuII* for *INS*, BRL) and 10 μg was electrophoretically separated in either 0.8% agarose and Oncor buffer (*HRAS*), 1.0% agarose and TBE (insulin alleles A, B, C, E, F), or 1.0% agarose and Oncor buffer (insulin alleles D, G). The DNA was transferred by vacuum to nylon membranes (Oncor). Probes for *HRAS* (pEJ 6.6) and *INS* (phins 310) were obtained from American Type Culture Collection (Rockville) and labelled by the random primer method[22] using [α-^{32}P]dCTP (Amersham). Hybridization was carried out at 45 °C overnight using the appropriate probe and Hybrisol I (Oncor) with poly-A RNA (10 μg ml^{-1}) and denatured *E. coli* DNA (100 μg ml^{-1}) added. Membranes were washed three times in 0.1% SDS, 0.1×SSC at room temperature for 15 min, followed by one wash at 52 °C for 1 h. Autoradiography was performed using Kodak XAR film and enhancing screens. Films were read independently by two people unaware of the diagnoses.

schizoaffective disorder, unipolar depressive disorder, cyclothymia, dysthymia or depressive neurosis and various personality disorders with and without affective symptoms As pedigree 110 and its extensions include a number of individuals with these psychiatric diagnoses (Fig 1), which may (or may not) be genetically related to bipolar affective disorder, a diagnostic hierarchy was developed to include such individuals in the linkage analysis This hierarchical system has two dimensions The first measures severity of affective symptoms and has four categories (Table 3) The other dimension includes milder syndromes in the affected phenotype by allowing for both a criteria-based system such as the RDC (as was used in the initial study, ref 9) as well as the clinical impressions of psychiatrists on the review board The diagnostic hierarchy used in the present study (Table 3 legend) was developed by members of the psychiatric review board who were unaware of the genotypes of any of the members of the pedigree

Genotyping and linkage analysis

Genotyping was performed independently in two laboratories (NIMH and St Louis) Genomic DNA was extracted from lymphoblastoid cell lines obtained from the Coriell Institute for Medical Research[16] for 120 members of Amish pedigree 110 (Fig 1 and Table 2) In one laboratory (St Louis), DNA for some family members was extracted directly from blood The methodology for DNA extraction and Southern analysis differed slightly between the two laboratories (see legend Fig 1) A consensus was obtained on all typings, however, with the exception of one individual (III-20) Resolution of this single discrepant genotype will require obtaining a new DNA sample on individual III-20 as each laboratory was able to confirm their typing on several occasions from their original source of DNA, indicating that an error had occurred in the handling and (or) storage of lymphocytes for this subject Nevertheless, the linkage analyses were performed twice using each genotyping for this subject without any effect on the lod scores (data not shown)

TABLE 1 Age-specific penetrances used for multipoint linkage analyses

Age	Liability class	Probability of disease AA	Aa	aa
0–14	1	0 0001	0 0001	0
15–19	2	0 18	0 18	0 0001
20–24	3	0 42	0 42	0 001
25–29	4	0 73	0 73	0 001
⩾30	5	0 85	0 85	0 001

Values represent age- and genotype-specific penetrances of the Major Affective Disorder (MAD) phenotype AA represents an individual homozygous for the disease alleles, Aa represents heterozygotes, and aa represents individuals genotypically normal at the MAD locus

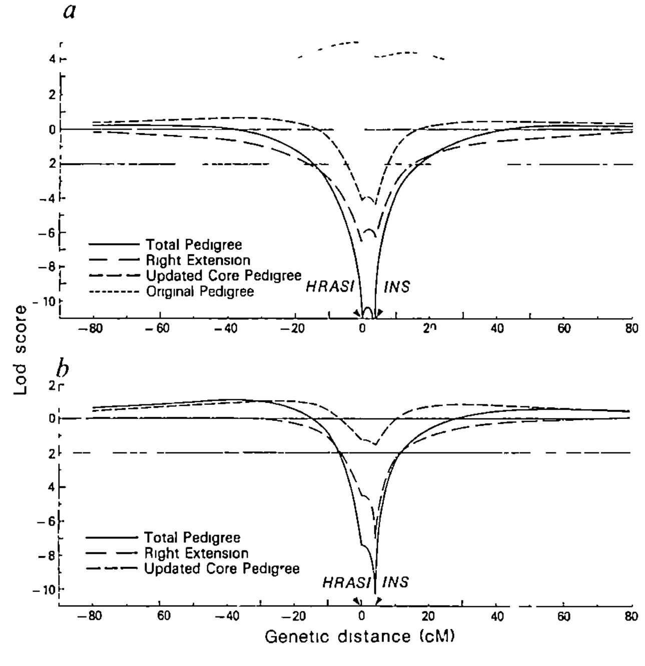

FIG 2 Multipoint linkage analysis using *A*, the original diagnostic criteria and *b*, the diagnostic system which includes broader diagnostic criteria to define the affected phenotype System A is equivalent to system number 3 (RDC) from Table 3, and includes affected individuals with bipolar disorder, major affective disorder and schizoaffective disorder, but not minor depression System *B* is identical to system 2 using clinical criteria from Table 2 It includes as affected those with bipolar, schizoaffective or recurrent unipolar major affective disorders, but excludes those with minor depression or only a single episode of major depression For each diagnostic system, the data has been analysed for the updated core pedigree, the right extension and the total pedigree Three-point analyses to determine the most likely location of the locus for bipolar affective disorder in relation to *HRAS* and *INS* were performed using the LINKMAP subroutine of LINKAGE version 4 8 (ref 20) For these analyses, the distance between *HRAS* and *INS* was held constant at 3 8 cM (ref 23) Five liability classes were defined (see Table 1) The recombination distance between *HRAS* and *INS* was examined in each portion of the pedigree and found to be consistent with other estimates[23]

Four *HRAS* alleles (about 5 2 kilobases (kb) long (1), ~5 7 kb (2), ~6 2 kb (3), ~6 8 kb (4)) and four *INS* alleles (about 760 bp (A), ~800 bp (B), ~830 bp (C), ~2 35 kb (D)) were delineated as described in the original study[9] Three additional *INS* alleles (~650 bp (E), ~820 bp (F), ~2 5 kb (G)) were also observed, primarily in the extensions of the core pedigree The microheterogeneity observed at the *INS* locus is consistent with other population studies of this gene[17]

Analyses of the cosegregation of alleles at the *HRAS* and *INS* loci with the bipolar affective disorder phenotype were performed using the computer programs LIPED[18,19] and LINKAGE[20] (see Table 2 legend) Analysis of linkage between affective disorder and each marker was done for the original core pedigree, the updated core pedigree, the right extension and the complete pedigree Five liability classes were defined and the age-specific penetrances for the multipoint linkage analysis are shown in Table 1

Linkage in the updated core pedigree

In the course of our study we (J K , E G , S B , A G , R L , G C and S P, unpublished data) independently reanalysed the original core pedigree with the affection status and diagnoses used in the initial study, but with the genotypes from the NIMH laboratory, and identical lod scores were obtained The genotypes of 2 new unaffected family members (II-20, 21) added into the core pedigree had only a minor effect on the lod scores The addition of genotypes for 10 unaffected individuals, however, who were incompletely genotyped in the original analysis (data from only one of the two marker loci were available), resulted in a significant change in the lod scores for both *HRAS* and *INS* The maximum lod score for *HRAS* decreased from 4 08 at $\Theta = 0$ to 2 46 at $\Theta = 0\ 05$, whereas that for *INS* increased from 2 63 to 3 38 at $\Theta = 0$ (Table 2)

The most dramatic effect on the lod scores resulted from the addition of updated diagnostic information on two family members who became ill after the original study, one (IV-20) developed a manic psychosis (bipolar affective disorder, type I) and the other (III-21) suffered a severe depression with catatonic features (major depressive disorder) Together, these changes lowered the interpolated maximum lod scores to 1 03 at $\Theta = 0\ 17$ and 1 75 at $\Theta = 0\ 14$ for *HRAS* and *INS*, respectively (Table 2) The addition of the left extension to the core pedigree (updated core) further reduced the lod scores to a maximum of 0 70 at $\Theta = 0\ 20$ and 1 29 at $\Theta = 0\ 20$ for *HRAS* and *INS*, respectively (Table 2)

TABLE 2 Lod scores resulting from sequential expansion of the core pedigree

6 Total (4+5, *N*=120)	−7.75	−6.71	−2.40	−1.07	0.19	0.55

The original core pedigree is identical in membership, genotypes and diagnoses to that reported originally[9]. Each subsequent analysis includes the information in the previous one plus the additional data as indicated. The new genotypes include 10 *HRAS* and *INS* genotypes which were not available at the time of the original study. The updated diagnoses refer to two individuals who had an onset of major affective disorder subsequent to the initial analysis (IV-20, bipolar I disorder, II-21, major depressive disorder). Analyses of the cosegregation of alleles at the *HRAS* and *INS* loci with the bipolar affective disorder phenotype were performed using the computer programs LIPED[18,19] and LINKAGE[20] on a COMPAQ Deskpro 386 microcomputer and a VAX 8800. All pairwise analyses (*HRAS* × *INS*, *HRAS* × affective disorder, *INS* × affective disorder) used LIPED. Analyses were performed assuming an autosomal dominant transmission model. For the two-point analyses, the probability of exhibiting the affected phenotype for individuals who inherited the predisposition allele for bipolar affective disorder was modelled as a linear function of age with a penetrance of 0 at age 15 and a maximum penetrance of 85% reached at 35 years of age. The maximum penetrance for the nonsusceptible genotype was 0.1%, reached at 35 years of age. The allele frequency of the disease-predisposition allele was taken as 0.021 for all analyses. The *SstI HRAS* allele frequencies were 0.30, 0.30, 0.10, and 0.30 for alleles 1, 2, 3, and 4, respectively. Genotypes at the *INS* locus were reduced to a four-allele system to maximize efficiency of computing time. The latter involves no loss of information in the analyses. All alleles were considered as equally likely.

Linkage in the right extension

When analysed alone, the lod scores for linkage between either the *HRAS* or *INS* loci and bipolar affective disorder in the right extension were strongly negative (Table 2); linkage can be excluded for $\Theta \leq 0.05$. Similarly, when the right extension and core are considered together, linkage can be excluded for $\Theta \leq 0.10$ for *HRAS* and $\Theta \leq 0.05$ for *INS*. The lod scores at $\Theta = 0$ represent odds of 10^{10} and 10^{8} against close linkage between a disease locus and the *HRAS* and *INS* loci, respectively.

Alternative diagnostic criteria

Linkage analyses were done using alternative diagnostic criteria (clinical consensus diagnoses) as outlined in Table 3 on the core pedigree. The strongest evidence for linkage was obtained when all individuals with mania, hypomania or recurrent major depression were considered affected and when clinical, as opposed to RDC, diagnoses are used (maximum lod score for *INS* of 2.88 at $\Theta = 0$) (Table 3). Inclusion of individuals with minor depression decreased the lod scores for both *HRAS* and *INS*.

Multipoint linkage analysis

Illustrated in Fig. 2*a* are the results of the multipoint linkage analysis between *HRAS*, *INS* and a locus for bipolar affective disorder using RDC diagnostic criteria. Linkage was excluded in the interval between *HRAS* and *INS*, as well as to within 5 cM on either side of each of these markers for the updated core pedigree. Both the right extension alone and the total pedigree gave exclusions to within 15 cM on either side of the *HRAS*-*INS* interval.

Figure 2*b* illustrates the multipoint linkage results when a clinical (as opposed to RDC) diagnostic system is used to define the affected phenotype including mania, hypomania and recurrent major depressive disorder. Using this diagnostic system, linkage could not be excluded in the core pedigree alone; the maximum lod score was $\sim$1.0 at 26 cM distal to *HRAS*. Linkage could be excluded in the right extension and in the total pedigree within the interval between *HRAS* and *INS* and to within 7 cM on either side of the markers.

Discussion

The initial linkage analyses of pedigree 110 reported by Egeland *et al*[9] provided strong evidence for a locus conferring a predisposition to manic-depressive illness on chromosome 11p15. These investigators reported a lod score of 4.08 at $\Theta = 0$ in the two-point analyses between *HRAS* and bipolar affective disorder. The multipoint linkage analysis using both markers, *HRAS* and *INS*, yielded a lod score of $\sim$5 (odds of 10^5 to 1 in favour of linkage). In our reanalysis, the recent onset of affective disorder in 2 members of the pedigree and the addition of genotypic data on six individuals in a newly included sibship, and on ten previously incompletely genotyped members, markedly reduces the statistical probability of linkage in both the two-point and multipoint analysis (Table 2 and Fig. 2).

Linkage between bipolar affective disorder and the *HRAS* and *INS* loci can also be excluded in the large lateral extension of pedigree 110. This observation can be interpreted in at least two ways: that there is genetic heterogeneity among the Old Order Amish, and/or that, if it is assumed that the illness in the original core and this extension is genetically homogeneous, there is strong evidence against linkage of a susceptibility locus for bipolar affective disorder to this region of 11p15. Although the Old Order Amish represent a genetic isolate, it has been suggested (J. A. Egeland, personal communication) that multiple genes may be responsible for affective disorder within the Amish population as several progenitor couples had mental illness among their first and second generation descendants. The analysis, therefore, of a large portion of the core pedigree may be complicated by the presence of two different genes responsible for affective illness.

What then is the evidence that bipolar affective disorder is linked to the *HRAS* and *INS* loci in the Old Order Amish? The hypothesis that has been tested so far is that the inheritance of specific alleles at a locus on chromosome 11p15 linked to *HRAS* and *INS* is a necessary condition for the occurrence of affective disorder in the members of pedigree 110. This hypothesis has been rejected in the analysis of the extended pedigree. Alternative hypotheses consistent with the expanded data set and analysis include the possibility that linkage to 11p15 markers in the

The effect of different diagnostic criteria on the lod score analysis in the updated core pedigree. These data were calculated from a version of the updated core pedigree that lacks the small left extension, but includes all other updated information. See the legend of Table 2 for details of the two-point linkage analyses. Various diagnostic criteria (RDC, clinical) were used by the psychiatric review board who were blind to genotypes or the effects of diagnoses on the lod scores. The hierarchy is devised along two dimensions: one is based on the degree of relatedness of a given diagnosis to bipolar affective disorder, the other is based on whether the diagnoses were made by RDC criteria or by the clinical impressions of the review board. For each diagnostic system, lod scores are reported for both RDC and clinical diagnoses. The first diagnostic system includes as affected only those individuals who have had mania or hypomania. The next adds those individuals who have had multiple episodes of major depressive disorder (MDD), followed by a system that includes those who have had only a single episode of MDD. The final diagnostic system includes any individual who has had a diagnosis of minor depressive disorder, which requires fewer symptoms than major depression.

core is due merely to chance. Many other DNA markers have been tested in the core pedigree but no evidence for linkage has yet been found[21]. Testing of markers spanning the remainder of the genome will lead to the identification of the site of this locus, if a single major locus hypothesis is correct. Even a complete systematic evaluation of pedigree 110, however, using highly polymorphic markers spaced very closely and covering the entire genome may not resolve the issue. If genes at more than one locus can independently lead to genetic susceptibility to affective disorder in this pedigree, then conventional linkage analysis over the entire pedigree will continue to be problematic. It may, therefore, be impossible to generate a strong positive lod score over the entire pedigree for linkage of a single major affective disorder locus to any marker.

Another important consideration is the possibility that non-genetic factors may contribute to the aetiology of affective disorder in pedigree 110. Any individual in whom illness was significantly mediated by environmental rather than genetic factors has an even chance of appearing as a recombinant in a linkage analysis. If the frequency of such phenocopies is low, then their impact on statistical tests of genetic hypotheses may not be great, unless they happen to occur in a critical part of the pedigree. As the frequency of such individuals increases, however, their impact on the tests of genetic hypotheses may become increasingly significant. This may be particularly problematic when diagnostic categories are broad and the population frequency of individuals considered affected becomes correspondingly high. The use of narrower or alternative diagnostic criteria may reduce the frequency of phenocopies and hence the probability of observing chance recombination. Until a systematic analysis of the entire genome has been completed, it will not be possible to determine the extent to which these problems confound the identification of loci which contribute to the aetiology of affective disorder in pedigree 110.

Our analyses highlight many of the problems that can be anticipated in genetic linkage studies of common and complex neuropsychiatric disorders. Foremost among these are the probable presence of genetic heterogeneity even in relatively isolated populations and the presence of phenocopies, especially in large pedigrees such as in the Amish. Longitudinal follow up and reanalysis of the data incorporating unaffected members of the pedigree who subsequently become ill are essential, given the variable age of onset for psychiatric disorders. Molecular genetic studies of psychiatric disorders will continue to encounter these problems and efforts to reduce their impact will be critical. ☐

Scanning from an independently specified branch point defines the 3′ splice site of mammalian introns

Christopher W. J. Smith, Elena B. Porro, James G. Patton & Bernardo Nadal-Ginard

Laboratory of Molecular and Cellular Cardiology, Howard Hughes Medical Institute, Department of Cardiology, Children's Hospital, and Departments of Pediatrics and Cellular and Molecular Physiology, Harvard Medical School, Boston, Massachusetts 02115, USA

During pre-messenger RNA splicing the lariat branch point in mammalian introns is specified independently of the 3′ splice site by the sequence surrounding the branch point and by an adjacent downstream polypyrimidine tract The 3′ splice site is dispensable for spliceosome assembly and cleavage at the 5′ splice.site, and is itself determined by a scanning process that recognizes the first AG located 3′ of the branch point/polypyrimidine tract, irrespective of distance or sequence environment

THE splicing of pre-messenger RNA involves the accurate and efficient removal of introns to produce mature mRNA which is a fraction of the size of the primary transcript The splicing reaction occurs by means of two consecutive transesterification steps[1] The RNA is first cleaved at the 5′ splice site, and a 2′-5′ phosphodiester bond is formed between the 5′ end of the intron and the 2′-OH group of a specific 'branch point' nucleotide within the intron In the second step, the 3′ splice site is cleaved, releasing the branched 'lariat' form of the intron, and the two exons are ligated together The *cis* information for splicing is restricted to limited regions of the transcript which interact with multiple RNA and protein factors to form a 'spliceosome' complex, in which the splicing reaction takes place[1-4] The GU and AG dinucleotides at the 5′ and 3′ intron boundaries are nearly invariant in higher eukaryotes, as is the A at the branch point[1,5-7] In addition, there is a consensus sequence around the 5′ splice site, $^{C}_{A}$AG-GURAGU (refs 6, 7), which is involved with base pairing to U1 small nuclear RNA (snRNA)[8], a stretch of pyrimidines typically located immediately upstream of the 3′ splice site and a weak mammalian consensus branch-point sequence, YNYURAY, which binds to U2 small nuclear ribonucleoproteins[9] (snRNPs) potentially by base pairing with U2 snRNA[5,10,11] In yeast there is an invariant branch point sequence, UACUA$\underline{\text{A}}$C, which base pairs with U2 snRNA (ref 10) Increasing the base pairing potential between mammalian branch points and U2 snRNA improves their efficiency[12-15] Nevertheless, many mammalian branch points bear little resemblance to the consensus, several lines of evidence, however, have led to the belief that the mammalian branch point is specified primarily by its proximity to the 3′ splice site, possibly by a device that measures distance from the AG dinucleotide at the 3′ intron boundary[5,16,1] First, most mammalian branch points have been mapped within 18–40 nucleotides of the 3′ splice site[5,16,18] Second, mutation of branch points can lead to activation of cryptic sites within the same distance[16,17] Third, some introns lack A residues within 18–40 nucleotides of the 3′ splice site, and use U or C residues instead, despite the clear preference for A residues[19] In addition, it has been shown that, to variable extents, mutation of the 3′ splice site AG can inhibit the first step in the splicing reaction, even though the 3′ splice site is not itself cleaved until the second step[18,20-23]

Although the definition of the 5′-splice-site consensus sequence and its recognition by U1 RNA is well characterized[8,24-26] the mechanism of recognition, relative importance and interactions of the 3′ splice site elements, including the branch point, polypyrimidine tract and the 3′ splice site AG, are poorly understood The recent reports of branch points at distances of >140 nucleotides from the 3′ splice site[27-29], clearly indicates that simple proximity to the 3′ splice site cannot be an obligatory determinant of branch-point location

We have now studied the mechanism of branch-point selection in the intron between the mutually exclusive exons 2 and 3 of the rat α-tropomyosin gene (*TM*) This intron has a branch point that lies 172 nucleotides upstream of the 3′ splice site (Fig 1*a*) The proximity of this branch point to the 5′ splice site of exon 2 enforces mutually exclusive behaviour, because splicing factors are unable to bind productively to the two elements and form an active spliceosome[27,28] Using this *TM* intron and the first intron of the human β-globin gene, we show that the branch point is specified independently of the 3′ splice site, by its immediate sequence context and by proximity to an adjacent polypyrimidine tract which may be distant from the 3′ splice site AG Efficient spliceosome formation, cleavage at the 5′ splice site and lariat formation require the polypyrimidine tract and branch-point sequence, but can occur in the complete absence of the 3′ splice site and exon The 3′ splice site itself is only recognized in the second step of splicing, and is in fact determined with reference to the branch point by a distance-independent scanning process for the first AG dinucleotide downstream of the branch point/polypyrimidine tract an extensive stretch of pyrimidines was still present 50–60 nucleotides downstream of the branch point (positions 162–211, Fig 1*a*) Further deletions bringing the branch-point sequence adjacent to this polypyrimidine tract restored splicing activity (Fig 2*a*, Δ44–157) This shows that a functional polypyrimidine tract does not have strict sequence specificity, and that to be active it requires an adjacent acceptable branch-point sequence

Branch-point sequence context

Branch point formation can occur at sequences that are highly divergent from the consensus sequence[16,17] Nevertheless, A residues, such as those at positions 156, 161 and 186 in the *TM* intron (Fig 1*a*), which have a suitable downstream pyrimidine tract, are not used as branch points under any conditions tested To test the role of sequence context in preventing the use of such nucleotides as branch points, the sequence around the A residue 28 nucleotides upstream of the 3′ splice site was converted to the strong branch-point consensus UACUAAC (ref 13) This mutation resulted in splicing of exon 2 to exon 3 in transcripts in which the normal branch point is too close to the 5′ splice site to be involved in branch formation (Fig 2*b*, UACUAAC 181) Thus the pyrimidine environment downstream of position 186 is sufficient to support splicing, given a suitable adjacent branch-point sequence The normal sequence at this position, CCCCCAC, is not an acceptable branch-point sequence, despite its having only two mismatches from the YNYURAY consensus The replacement of the five purines between the UACUAAC and the 3′ splice site with pyrimidines, thereby creating a 25-nucleotide continuous polypyrimidine tract, dramatically increased the efficiency of splicing and of 60S complex formation (UACUAAC 181Y) Thus, the sequence context of the branch point, and an adjacent polypyrimidine tract are involved in branch-point specification, and in determining the efficiency of the splicing reaction

Scanning for the 3′ splice site

Given that the specification of the branch point is independent of the 3′ splice site AG, the question arises as to the specification of the 3′ splice site itself Inspection of the *TM* intron shows that the 3′ splice site is the first AG dinucleotide downstream of the branch point and polypyrimidine tract (Fig 1*a*), as it is in other introns[5,29] Thus, the 3′ splice site could simply be recognized by 5′-to-3′ scanning for an AG, as originally suggested[6,34] To test this possibility, several mutants were constructed in which AG dinucleotides were inserted between the branch point and the 3′ splice site (Fig 3) In all cases, the intervening AG was used exclusively as the 3′ splice site The nature of the nucleotide preceding the AG, however, had a profound effect on the efficiency of the second step in splicing, CAG, UAG and AAG trinucleotides were used efficiently as 3′ splice sites (constructs ppR, p23Bg, p23Af) By contrast, GAG was inefficiently cleaved, although it was efficiently recognized, because downstream AG dinucleotides, including the normal 3′ splice site, were not used Moreover, a CAG-to-GAG mutation (pGAG, Fig 3) severely reduced the rate, but not the position, of cleavage at the normal 3′ splice site These results are compatible with the absence of GAG trinucleotides at natural 3′ splice sites[1,5,7] Deletion of the normal 3′ splice site AG (pΔAG) resulted in the exclusive and efficient use of the first AG in the 3′ exon, 178 nucleotides downstream of the branch point The distance between the branch point and the AG in these transcripts (75–178 nucleotides) had no effect on the efficiency of the second step of splicing (compare p23Bg and pΔAG) All the AG dinucleotides used in the above transcripts had a pyrimidine-rich environment immediately upstream, which could have been involved in specification of the 3′ splice site This is unlikely because conversion of the 30 nucleotides immediately upstream of the 3′ splice site in construct pGC+DX from 70% pyrimidine to 70% purine had no effect on either step in splicing (pR2, Fig 3) This confirms that the polypyrimidine tract is not obligatorily associated with the 3′ splice site Rather, it seems that the 3′ splice site is recognized by a simple scanning process for the first AG downstream of the branch point This is in agreement with the behaviour of some splicing mutants that use AG dinucleotides upstream of the normal 3′ splice site[18,34-37] One possible caveat is that the AG may need to be beyond a minimal distance (>18 nucleotides) from the branch point[5,34,38], presumably because of the steric constraints of factors bound at the branch point and polypyrimidine tract Also, in some cases more than one of a series of closely spaced AG dinucleotides is used as a 3′ splice site (ref 39, and R Reed, personal communication) Nevertheless, in these cases it is the upstream site that is predominantly used[39]

In a preliminary investigation of the nature of the scanning process, we tested whether stable secondary structure between the polypyrimidine tract and the 3′ splice site interferes with the recognition of the 3′ splice site Insertion of a 48-nucleotide palindromic element downstream of the polypyrimidine tract resulted in a block in the second step of splicing (p23HP, Fig 3) The presence of stable secondary structure was confirmed by the resistance to digestion with RNAse H in the presence of

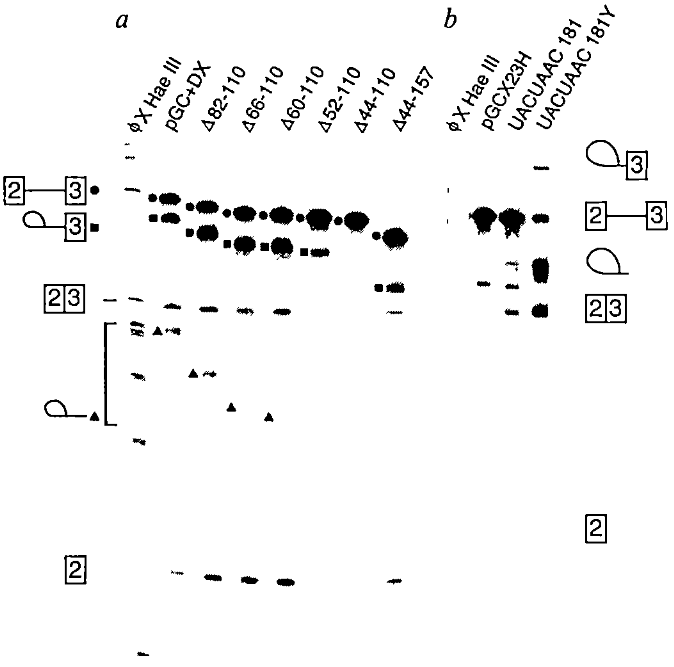

FIG 2 Branch-point specification by adjacent polypyrimidine tract and by sequence context *a*, Effect of polypyrimidine-tract deletions Templates containing specific intron deletions were constructed by deleting between the *AccI* site at position 110 (see Fig 1*a*) and *AccI* sites introduced by oligonucleotide directed mutagenesis with polymerase chain reaction (PCR) amplification, at the indicated positions The structure of mutagenized and amplified DNA was verified by sequencing The templates all contained the spacer element at the 5′ end of the intron, as in plasmid pGC+DX Splicing reactions were carried out and analysed as in Fig 1*b* Two-hour splicing reactions are shown *b*, Branch-point sequence context is important for splicing Constructs containing the native non-splicing intron with no spacer element at the 5′ end (pGCX23H), and with the sequence context of the A residue at position 186 changed from CCCCCAC to UACUAAC (UACUAAC 181 and UACUAAC 181Y) were used as templates for transcription UACUAAC 181Y also had all purines between the 3′ splice site and UACUAAC sequence converted to pyrimidines (U at positions 192, 199 and 205, C at positions 194, 202 and 206) The products of 2-h splicing reactions are shown The only band appearing in the plasmid pGCX23H lane corresponds to a block to endogenous exonuclease activity by factors bound at the branch point[27] The identities of lariat bands produced by the UACUAAC-element-containing transcripts were verified by debranching reactions

oligonucleotides complementary to one side of the stem (data not shown) Transcripts containing either half of the palindromic sequence alone were, by contrast, efficiently spliced (data not shown) Thus, secondary structure seems to be capable of blocking the scanning process that locates the 3′ splice site This result precluded our testing the requirement for a continuous phosphodiester backbone by a *trans* splicing experiment[40], because the complementary elements necessary to bring the two half-transcripts together would themselves block the scanning process In yeast introns, potential secondary structure-forming elements were found to inhibit the second step in splicing when adjacent to the branch point, but not when further downstream[41] Irrespective of secondary structure, however, insertions between yeast branch points and 3′ splice sites decrease the efficiency of the second step in splicing[41,42], indicating some difference in the mechanism of 3′ splice site recognition in yeast and mammals

Generality of specification mechanisms

To test the generality of our findings with the α-TM intron we made several constructs by using the first intron of the human β-globin gene A 120-nucleotide spacer element derived from the *α-TM* intron, chosen because it lacks any cryptic branch points or 3′ splice sites[27], was inserted between the globin gene polypyrimidine tract and 3′ splice site (Fig 4, BP BAM) This intron was still spliced, albeit with reduced efficiency The correct globin splice sites and branch point, now 155 nucleotides upstream of the AG, were used, showing that the branch point need not be in proximity to the 3′ splice site The reduced splicing efficiency could be due to the increased distance of the branch

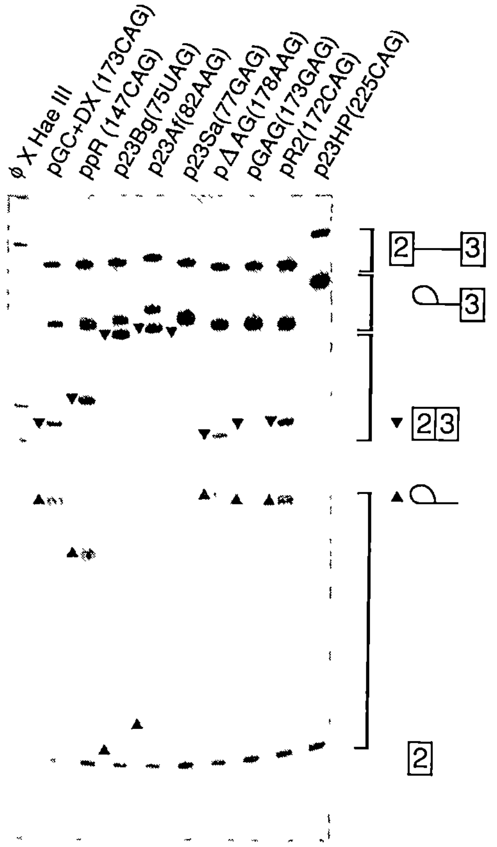

FIG 3 The 3′ splice site is specified as the first AG 3′ of the polypyrimidine tract Constructs with AG dinucleotides inserted between the polypyrimidine tract and 3′ splice site of the pGC+DX template were prepared Plasmid ppR had intron positions 186–213 changed to AGGCGCGTACGGGCACGGAAAACGAACAG Plasmids p23Bg, p23Sa and p23Af had the linker sequences AGATCT, CGAGCTCG and GCACTTAAGTGC inserted into the *Acc*I site at position 110, respectively pΔAG had the AG of the 3′ splice site deleted and, in addition, positions 181–187 changed to UACUAAC The UACUAAC was not used as a branch point in this transcript because of competition from the native branch point Transcripts with an AG-to-GG mutation in the 3′ splice site and no UACUAAC sequence have given identical results Plasmid pGAG had a C-to-G mutation at position 211 Plasmid pR2 had the A residue at position 186 deleted, and positions 187–213 changed to GACGCGTACGGCACGGAAAACGAACAG Plasmids ppR pΔAG, pGAG and pR2 were all cloned by oligonucleotide-directed mutagenesis with PCR amplification as in Fig 2 Plasmid p23HP had the 48-nt palindromic sequence, GGG(CGG)$_6$GAATTC(CCG)$_6$CCC cloned into the *Acc*I site at position 110 Each lane shows the products of a 2-h splicing reaction, and is labelled with the name of the construct and the position downstream of the branch point, and the sequence of the first AG-containing trinucleotide

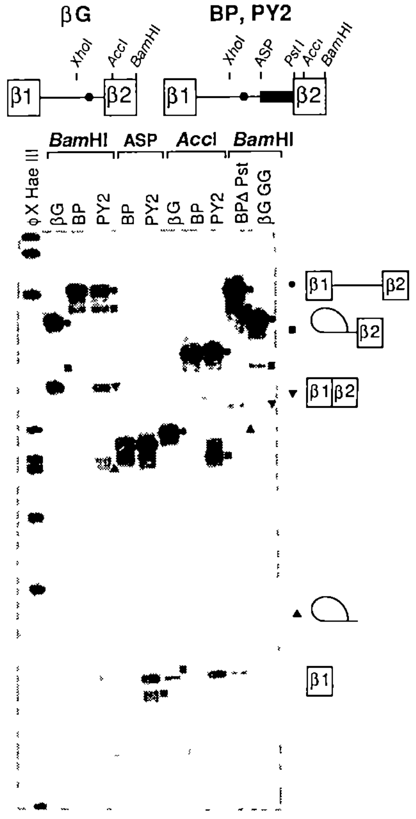

FIG 4 Branch point and 3′ splice site selection in β-globin transcripts Transcripts were produced containing the first intron of the human β-globin gene and the flanking exons (βG) Template BP was derived from the parent βG-containing construct RR108 by inserting nucleotides 111–213 of the *α-TM* intron (shown by the thick line in the schematic diagram) between the β-globin polypyrimidine tract and 3′ exon Template BP was constructed by PCR amplification of a fragment from the *Xho*I site upstream of the β-globin branch point, up to, but not including the 3′ splice site AG, followed by an ASP718 and an *Eco*RV site, nucleotides 111–213 of the *TM* intron with the final 6 nt changed to a *Pst*I site, and globin exon 2 up to the *Acc*I site The *Xho*I-*Acc*I fragment was cloned back into the parent globin framework Construct PY2 was derived from BP by the replacement of the six purines between the β-globin branch site and the ASP718 site with T residues, by oligonucleotide-directed mutagenesis with PCR amplification Construct BPΔPst had the 3′ splice site of BP removed by blunt-ending the *Pst*I site and re-ligating Construct βG GG was obtained by deleting between the *Kpn*I (ASP) and *Pst*I sites of BP leaving a single A-to-G change in the 3′ splice site of βG Transcripts were produced from templates linearized at the *Bam*HI, *Acc*I and ASP718 sites The products of 2-h splicing reactions are shown The identities of all lariat bands were verified by debranching and the branch point used by βG and BP (shown by the dot) was verified by primer extension with reverse transcriptase

Crystal structure of chaperone protein PapD reveals an immunoglobulin fold

Anders Holmgren & Carl-Ivar Bränden

Department of Molecular Biology, Biomedical Centre Box 590, S-751 24 Uppsala, Sweden

The chaperone protein PapD mediates assembly of pili in *Escherichia coli* Its polypeptide chain folds into two immunoglobulin-type domains that are homologous in sequence to the human lymphocyte differentiation antigen Leu-1/CD5

UROPATHOGENIC *Escherichia coli* carries an operon of 11 genes[1-3] for synthesis and assembly of pap pili which mediate attachment of the bacteria to eucaryotic cell surfaces One of these genes, *PapD*, codes for a chaperone protein which mediates assembly of pili by forming soluble multimeric complexes with pili subunits as an intermediate step in the assembly process[4] We report here the crystal structure of PapD to 2 5 Å resolution

The crystal structure of PapD

The PapD protein was crystallized in an orthorhombic space group $P2_12_12_1$ with cell dimensions $a = 58$ 2 Å, $b = 64$ 0 Å and $c = 67$ 0 Å, with one molecule in the asymmetric unit[5] The processed protein was purified from an *E coli* expression system and included the region of the gene encoding the signal peptide X-ray data to 2 5 Å resolution were collected on a Xentronics area detector A multiple isomorphous replacement (MIR)/anomalous electron density map was calculated using three heavy metal derivatives giving an average figure of merit of 0 66 Phasing statistics are given in Table 1 The polypeptide chain was traced using the Bones option in Frodo[6] The amino-acid sequence[4], as predicted from the complementary DNA sequence, was fitted into the map using the aromatic side chains as reference points (Fig 1) The structure has been initially refined using Xplor[7] on an Alliant Fx/4 computer giving an *R*-factor of 0 24 with no water molecules added The current model of 218 residues leaves no regions of the MIR map unassigned The amino acids of the model are numbered from 22 to 239 to conform to the numbering of the published sequence with the leader peptide (1-21) included Coordinates of the current model have been deposited in the Brookhaven Protein Data Bank

The structure of PapD is built up from two globular domains oriented such that the complete molecule has the shape of a boomerang (Figs 2 and 4) The two domains have very similar structures with an antiparallel beta-barrel structure formed by two beta sheets packing against each other The topology of each domain is the same as the constant domain of immunoglobulin molecules, comprising seven anti-parallel beta strands, A to G (ref 8) Both domains lack the disulphide bridge between beta strands B and F which is usually but not always found in immunoglobulin domains[8] The residues that form the beta strands are given in Fig 2*b*

The N-terminal domain comprises residues 22-121 Two long loop regions are present at one end of the barrel between strands C and D (residues 62 to 73) and between strands E and F (residues 94-106) The other loop regions are either reverse turns or short loops comprising three to five residues

Residues 153 to 239 form the C-terminal domain In addition to the seven beta strands A to G of the immunoglobulin fold there is a short beta strand H at the C-terminal end of the polypeptide chain which is positioned between, and is antiparallel to, beta strands G and A (Fig 2) This beta strand is firmly linked to strand G by a disulphide bridge between Cys 228 and Cys 233 The four residues between these cysteines

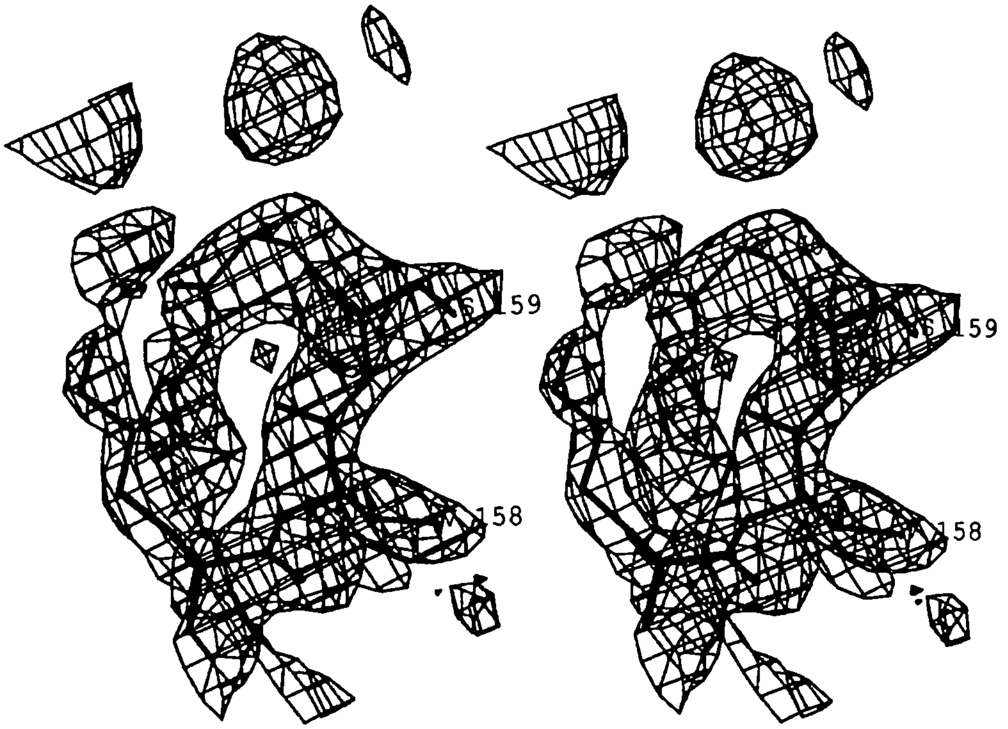

FIG 1 Representative electron density map showing a reverse beta-turn between strands A and B in the C-terminal domain

PapD was isolated from the periplasm of an *E coli* strain containing a cloned *papD* gene under the influence of the *tac* promoter[4], thereby forcing the bacteria to overproduce the protein PapD was collected from the periplasmic space and purified by the method of Lindberg *et al*[4] with some modifications[5] Crystals of PapD were obtained by the hanging drop method of vapour diffusion using a protein concentration of 12 mg ml^{-1} (ref 5), and 15% polyethylene gylcol 8000 as precipitating agent Crystals appeared after a few days and usually grew to a size of 0 5 mm in all directions X-ray data were initially collected to 5 0 Å on a single counter four circle diffractometer Analysis of difference Patterson maps was undertaken using the program RSPS (written by Stefan Knight), which provided the heavy atom positions for the major site in the three derivatives used and indicated some minor sites of low occupancy The heavy-atom positions were further refined using the program Heavy in the CCP4 program package from Daresbury UK Difference Fourier maps, calculated by the program Protein[21], revealed some additional minor sites X-ray data to 2 5 Å resolution were collected for those derivatives which gave good refinement statistics on a Xentronics multiwire area-detector[22], using the software system described by Blum *et al*[23]

form a short hairpin loop between strands G and H The sulphur atoms of this disulphide bridge (Fig 3) are oriented towards the hydrophobic core of the barrel and do not react with heavy metal reagents The linker region between the domains, residues 122 to 152 contains a number of hydrophobic side chains which form a hydrophobic core in the central region of the molecule Additional residues in this hydrophobic core are provided by loop regions from both domains Secondary structure elements in relation to the amino-acid sequence of PapD are given in Fig 5

Structural similarity with immunoglobulins

To determine whether the topological similarity between the PapD and immunoglobulin domains also reflects structural similarity, we have compared these domain structures using the HOMO program[9] The alpha carbon atoms of the two PapD domains were superimposed with each other and with the constant domain CH2 of an IgG Fc-fragment[10] We found that 50 alpha carbon atoms of the PapD domains superimpose with each other with a root mean square error (r m s) of 3 5 Å, showing that only about half of the residues that build up the two domains are structurally equivalent These residues build up the core of the domains An r m s value of 3 5 Å for superposition of the cores of two structurally equivalent domains is compatible with the fact[4] that there is no amino-acid homology between these two domains[11]

In contrast to the above results, the cores of 50 alpha carbon atoms of PapD domains 1 and 2 superimpose with CH2 with r m s values of 2 1 and 2 5 Å respectively Each PapD domain is thus more similar in structure to the immunglobulin domains than they are to each other They seem to be two different variations of the CH2 core structure In both these PapD domains the beta strands are arranged in two distinct beta sheets, similar to the arrangement in all immunoglobulin structures[8] and different from that in other structures of the same topology such as superoxide dismutase, which is more like a barrel[12]

Sequence homology with CD5-antigen

There is no significant amino-acid sequence similarity between CH2 and the PapD domains To examine if other members of the immunoglobulin superfamily are homologous to PapD we searched in the NBRF protein-sequence data base (Protein Identification Resource), and found that amino-acid residues −4 to 252 of the Leu-1 human lymphocyte differentiation antigen also called CD5 (ref 13), could be aligned with the sequence of the complete PapD molecule giving a 26% identity All gaps

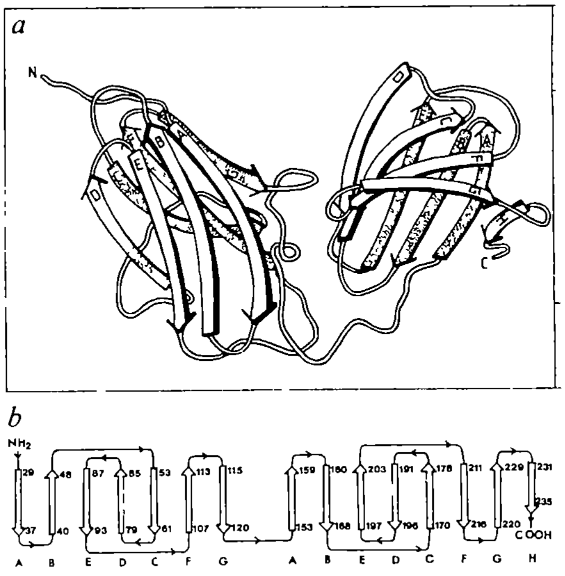

FIG 2 *a*, Schematic diagram of the PapD molecule, showing the arrangement of the beta strands in the two domains Strands A B E form one beta sheet and strands C F G form a second beta sheet which is packed against the first sheet Dotted strands belong to the sheet at the back of the figure Beta strand D of the N-terminal domain belongs to both beta sheets by forming hydrogen bonds to strand C at the beginning and to strand E at its end *b*, Topology diagram of the course of the polypeptide chain of PapD Residue numbers that form approximate beginnings and ends of the beta strands are given starting with residue 22 which is the first residue after the signal peptide and another area of three acidic residues on the C-terminal domain (E185, E186, E188). We suggest that this region is involved in binding the pili subunits. This model of the interaction area forms the basis for specific mutagenesis work, now in progress.

The amino-acid-sequence homology between *E. coli* PapD and human Leu-1/CD5 raises some puzzling evolutionary questions. The rate of evolution in the CD5 proteins is quite fast, as the functionally homologous CD5 proteins in human (Leu-1)

show rather low sequence identity, from 43% in domain 1 to 58% in domain 3. The possibility of divergent evolution from a common ancient bacterial ancestor therefore seems to be excluded. It is more likely that horizontal gene transfer has occurred at a much later stage in evolution. Genes involved in eukaryotic cell–cell interactions may have been recruited by bacteria to aid in their attachment to eukaryotic cells. Such gene transfer would also explain why a member of the immunoglobulin superfamily has been found in *E. coli* bacteria. □

The distribution of galaxies in the direction of the 'Great Attractor'

Somak Raychaudhury

Institute of Astronomy, University of Cambridge, Madingley Road,
Cambridge CB3 0HA, UK

THE discovery of galaxy streaming motions of up to 600 km s^{-1} towards Hydra–Centaurus has led to the suggestion[1] that this motion is induced by a concentration of galaxies (the 'Great Attractor') centred on galactic coordinates $l = 307°$, $b = 9°$ at a distance corresponding to $4{,}350 \pm 350$ km s^{-1} in the Hubble Flow. Here we present a map of ~17,000 galaxies down to $B_J = 17^m$ in an extended region of the sky in this direction. The clusters of galaxies identified from the map are shown to constitute two distinct concentrations in redshift (see, for example, ref. 2). We explore the possibility that the further of the two concentrations, centred near $l = 312°$, $b = 31°$, at a mean redshift of 14,000 km s^{-1}, is a major contributor to the peculiar motion of the Local Group. This is unlikely because the contribution to the dipole anisotropy of extragalactic light due to galaxies in this region, beyond a diameter limit of 1.3 arcmin, is about 10% of that due to nearer galaxies, and the concentration would need to have an extremely high mass-to-light ratio. Superclusters as massive as this would cause appreciable anisotropies in the cosmic microwave background radiation.

We have completed a survey of galaxies in an extended region around the proposed 'Great Attractor', using glass copies of UK Schmidt Telescope (UKST) Sky Survey plates (emulsion IIIa-J), which have been scanned by the SERC Automatic Photographic Measuring (APM) facility in Cambridge. The area covered (Fig. 1) consists of 103 such plates, each covering 5° × 5° of the sky. After preliminary star-galaxy separation, all galaxy candidates have been visually inspected, and morphological types assigned to the galaxies found. The magnitudes of galaxies on different plates have been reduced to a consistent system by using the galaxies in the $\gtrsim 1°$ overlaps between neighbouring plates. A catalogue of galaxies (the Hydra-Centaurus catalogue), which is $\gtrsim 97\%$ complete down to a magnitude limit of $B_J \simeq 17^m$, has been compiled. It consists of 16,963 galaxies, for which positions, relative magnitudes, diameters and various profile parameters have been measured: >80% of these being catalogued for the first time.

The galaxies in the Hydra-Centaurus catalogue are plotted in an equal-area projection in Fig. 1*a*. All the Abell-Corwin-Olowin (ACO) clusters[3] found in this region, along with some poor clusters, are indicated in Fig. 1*b*, and listed in Table 1. These figures can be compared with Fig. 2, which is a plot of all galaxies >1 arcmin in this region of the extragalactic sky, from existing catalogues (ESO, MCG and UGC: see Fig. 8 of ref. 1).

As large-scale redshift surveys in this area[4,5] have concentrated mostly on galaxies in the ESO catalogue (ref. 15) not many redshifts are found in the literature for galaxies beyond ~6,000 km s^{-1}. However, many clusters in this region out to 20,000 km s^{-1} have been studied in detail[6-10]. Figure 3 shows that almost all of these clusters belong to two distinct groups, with none between 5,000 km s^{-1} and 10,000 km s^{-1} in the area of interest. The nearer group is what is commonly known[11] as the 'Hydra-Centaurus Supercluster'. On the other hand, all the 14 clusters lying between $10{,}000 < v < 16{,}500$ km s^{-1} lie within 10° of A 3558 (Shapley 8: $l = 312°$, $b = 31°$), the mean redshift being $\langle v \rangle = 13{,}620$ km s^{-1}. The existence of an excessive concentration of galaxies in this region was first discovered by Shapley[12], and is referred to here as the 'Shapley Concentration'. This concentration has recently been pointed out in the distribution of galaxies[6], ACO rich clusters[2] and X-ray clusters[13].

Because both gravity and luminosity fall as the inverse square of the distance, the dipole moment of the distribution of galaxies (weighted by a function of their luminosities) has often been used[11,14] to estimate the peculiar acceleration of the Local Group. Using the expression $P = \sum_i D_i^2 \hat{r}_i$ as such an estimator, where D_i is the major angular diameter of a galaxy i, normalized to the ESO system[15] and corrected for galactic extinction[16], the 'optical dipole' has been estimated to be $P_{>1.3'} \approx 17{,}300$ (ESO arcmin)^2, directed towards $l = 257°$, $b = 34°$, from an all-sky catalogue of 16,886 galaxies having $D_{\mathrm{ESO}} > 1.3'$ (ref. 14, Table 1).

Here, we attempt to estimate the contribution of the galaxies in the Hydra-Centaurus catalogue, beyond the above diameter limit, to the optical dipole. To do this, we have calculated the value of

$$\mathscr{P}_{<1.3'} = \sum_{\text{fields}} \left[\left(\sum_j D_j^2 \hat{r}_j \right) - \langle \Delta^2_{\mathrm{SGP}} \rangle \hat{r}_{\mathrm{f}} \right],$$

where $\hat{r}_f$ refers to the unit vector in the direction of the centre of a UKST field and $\hat{r}_j$ the unit vector towards all galaxies j, with major (angular) diameter D_j in units of ESO arcmin, in that field. The dipole is normalized to the value of $\langle\Delta^2_{\rm SGP}\rangle$, which is the mean $\sum D^2$ per field derived from the 15,151 galaxies down to the same magnitude limit, compiled by the APM survey[17] from 185 UKST fields around the South Galactic Pole (Loveday, unpublished thesis, Univ. of Cambridge, 1989). In both cases, all galaxies in the range $0.5' \leq D_{\rm ESO} \leq 1.3'$ have been used. The underlying assumptions here are (1) that the dipole summed over the rest of sky is negligible, and (2) that the SGP value is a fair representation of the rest of the sky at that magnitude limit, being averaged over a very large area of sky (~1 sr) far away from the Hydra–Centaurus region. As the ESO catalogue and the APM catalogues (SGP, HC) measure their diameters to different isophotes, a mean linear relation between their diameters is estimated using the galaxies in common between the ESO catalogue and the APM catalogues. The angular diameters have been corrected for galactic extinction (ref. 16) A_B by a factor of $10^{0.2A_B}$.

For the 12,325 galaxies in the Hydra–Centaurus catalogue (103 UKST fields) satisfying $0.5' \leq D_{\rm ESO} \leq 1.3'$, we derive $\mathscr{P}_{<1.3'} \approx 3{,}242$ (ESO arcmin)^2, directed towards $l = 310°$, $b = 39°$, which is 19% of $\mathscr{P}_{>1.3'}$. One can, however, argue that a significant fraction of galaxies smaller than 1.3′ are actually intrinsically smaller galaxies associated with the known concentration of closer ESO galaxies. To estimate the effect of sample incompleteness that is due to a cutoff in apparent diameter, we assume a 'Light Incompleteness Function' of the form[11]

$$\mathscr{L}(d) = \frac{1 + t/2}{(1 + t/5)^4},$$

where $\mathscr{L}(d)$ gives the fraction of total luminosity emitted by galaxies of 'diameter' $\geq d$; and $t = (d/6{,}538)^2$, where $d = D_{\rm lim} \times \langle v \rangle$ km s^{-1} arcmin, and $D_{\rm lim}$ is the angular diameter (in the ESO system) down to which the sample is complete. To correct for galaxies at the faint end of the luminosity function beyond the diameter limit of a sample, one needs to multiply $\mathscr{P}$ by $\mathscr{L}^{-1}$.

It has been shown that more than half of the dipole that is due to galaxies larger than 1′ (ref. 11) comes from galaxies with $v < 2{,}000$ km s^{-1}, and 80% from those with $v < 4{,}000$ km s^{-1}. For the sake of estimating $\mathscr{L}^{-1}$, we assume that half of $\mathscr{P}_{>1.3'}$ comes from $\langle v \rangle = 2{,}000$ km s^{-1} and the other half from $\langle v \rangle = 3{,}500$ km s^{-1}, which gives $\mathscr{L}^{-1} = 1.11$. This indicates that more than half of $\mathscr{P}_{<1.3'}$ as estimated above comes from smaller galaxies that are in the nearer concentration. Accordingly, a similar correction should be applied to the further concentration

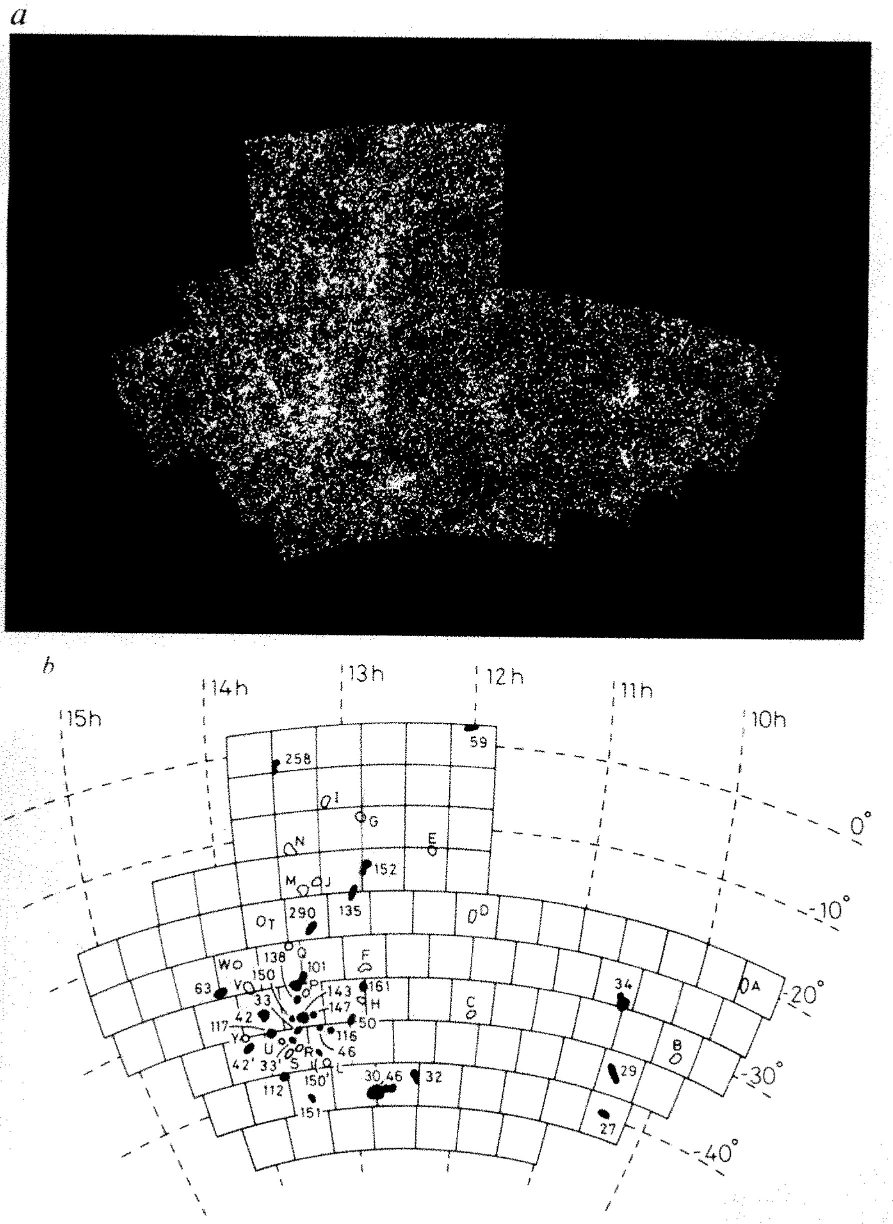

FIG. 1 *a*, An equal-area plot of the 16,963 galaxies in the Hydra–Centaurus catalogue down to $B_j = 17^m$. Each point represents a galaxy. Large chains of rich clusters, threaded with filamentary structures are clearly seen, especially in the region 12 h 40 min < α < 13 h 50 min, −35° < δ < −25°. *b*, The boundaries of the 103 UKST fields surveyed are shown, together with the positions of the clusters of galaxies identified in *a* and listed in Table 1. The numbers refer to the mean redshift of the clusters, where available, in units of 100 km s^{-1}. A right ascension–declination grid shows the position in the sky.

as well, to account for galaxies missed by the diameter limit of the Hydra–Centaurus catalogue. Because the latter is magnitude limited, its diameter limit is not well defined; however, we believe that it is fairly complete down to $D_{\rm ESO} = 0.5'$. Assuming that all the excess galaxies in the diameter range $0.5' \leq D_{\rm ESO} \leq 1.3'$ that belong to the further concentration are at $\langle v \rangle = 13{,}620\ {\rm km\ s^{-1}}$, we get $\mathscr{L}^{-1} = 1.42$. This means that the galaxies that are beyond a redshift of about $5{,}000\ {\rm km\ s^{-1}}$ contribute only $1.42 \times (0.19 - 0.11)/1.11 = 10\%$ of the dipole acceleration that is due to those that are nearer.

The fact that the Shapley Concentration lies very close to the proposed position of the 'Great Attractor' has prompted some authors[2,6] to consider the possibility of its being a major contributor to the peculiar motion of the Local Group. Here, we consider the extreme hypothesis that the Shapley Concentration is responsible for the entire peculiar motion of the Local Group (of $570\ {\rm km\ s^{-1}}$), for which it would have to have a mass of $M_{\rm GA} \approx 2.6 \pm 0.8 \times 10^{17}\ h^{-1}\ M_{\odot}$ at a distance of $136\ h^{-1}$ Mpc ($H_0 = 100\ h\ {\rm km\ s^{-1}}$). If all the 3,390 galaxies belonging to the Hydra–Centaurus catalogue, within a radius of 10° of Shapley 8 ($24\ h^{-1}$ Mpc at a distance of $136\ h^{-1}$) and smaller than $D_{\rm ESO} = 1.5'$, were placed at a distance of $136\ h^{-1}$ Mpc, and their magnitudes corrected for galactic extinction[16], then the total luminosity would be $L_{\rm J} = 4.1 \times 10^{13}\ h^{-2}\ L_{{\rm B},\odot}$, leading to $M/L_{\rm B} \approx M/L_{\rm J} \approx$

This table lists the galaxy clusters found in the APM Hydra–Centaurus Survey, indicated in Fig. 1b. The columns indicate: * the marker used in Fig. 1*b* (letters for clusters with no available redshift, numbers refer to redshift of the cluster in 100 km s^{-1}, except for those marked with an asterisk for which the redshifts were updated later); † 'Abell' numbers (from the ACO rich cluster catalogue[3]); ‡ position (1950), §‖ mean redshift with respect to the Local Group, and velocity dispersion, in km s^{-1}, where available (refs 6–10, and Quintana and da Souza, preprint); ¶ the number of galaxies used in estimating $\langle V_r \rangle$ and σ, if known; and ** Alternative names found in the literature (P, ACO poor clusters[3], K, Klemola[21]).

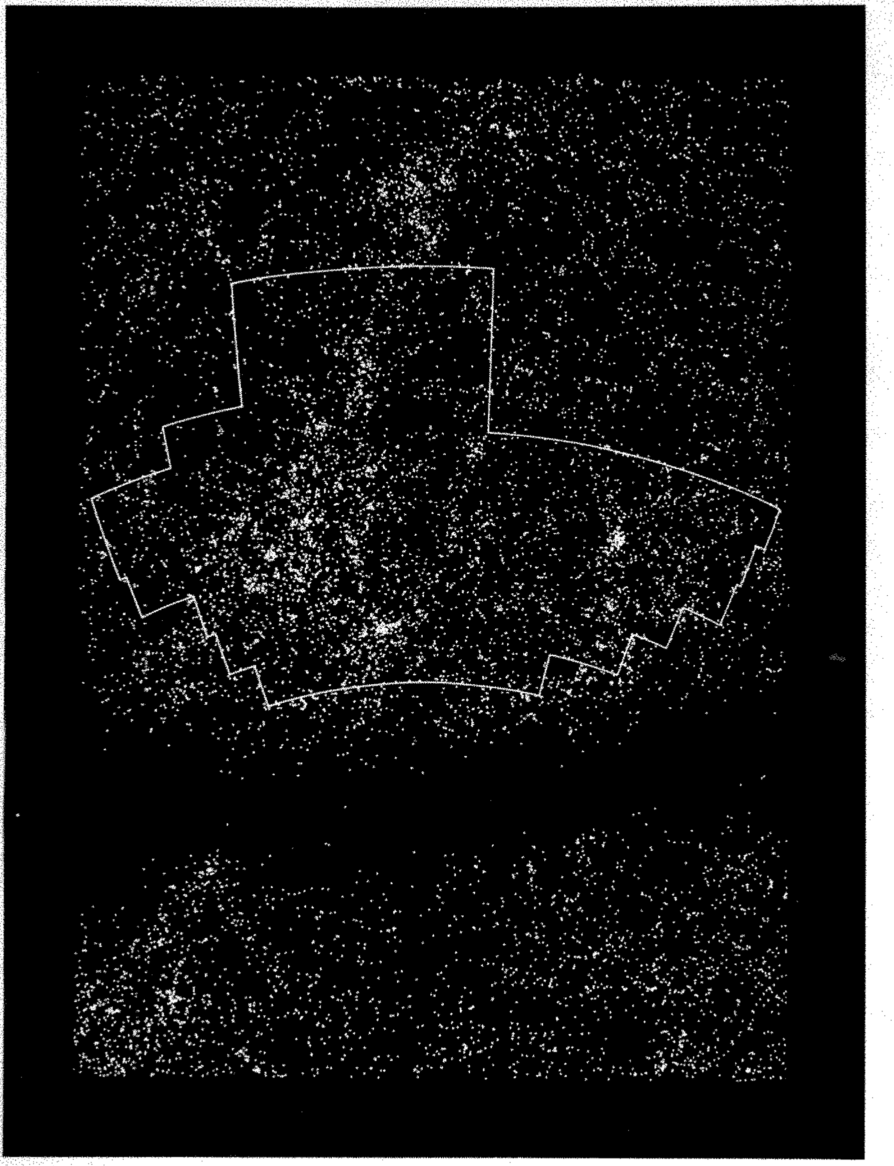

FIG. 2 An equal-area plot of all galaxies in the survey region and its immediate neighbourhood, as found in existing catalogues (a merged version of the ESO, MCG, UGC catalogues as used in Fig. 8 of ref. 1). The area enclosed by the survey region (outline indicated) contains 1,220 galaxies larger than $D_{\mathrm{ESO}} > 1.3'$. The cluster to the north of the survey area is the Virgo Cluster. The Supergalactic Plane runs across the plot, on either side of the galactic plane, the latter showing up as an empty 'zone of avoidance'. The nearby clusters ($\langle v_r \rangle <$ 5,000 km s^{-1}, such as Hydra I and Centaurus) are easily seen, but not those belonging to the further Shapley Concentration.

6,300 h (for comparison: $M/L_B \approx 1{,}500\,h$ for an $\Omega_0 = 1$ Universe). This makes the Shapley Concentration unlikely to be the Great Attractor, as it would also imply (1) that mass does not follow light, and dark matter prefers to reside in clusters and superclusters of galaxies rather than in the field, and furthermore, (2) that superclusters are capable of having higher mass-to-light ratios ($M/L_B \approx 6{,}000\,h$) than the richest clusters of galaxies (for example, Perseus: $M/L_B \approx 850\,h$). Both of these are against biasing arguments.

Furthermore, if the Shapley Concentration were a major source of the dipole acceleration of the Local Group, one would expect peculiar velocities to continue to rise beyond the nearer concentration of galaxies. However, preliminary results[18] from Dressler and Faber's survey in this region indicate that peculiar velocities of galaxies decrease beyond 4,000 km s^{-1}. The Hydra–Centaurus catalogue presented here can serve as a source for more extensive surveys of this kind.

Massive 'attractors' can have an appreciable effect on the cosmic microwave background radiation (CMBR). Rees and Sciama[19] showed that a nearby expanding (contracting) density enhancement, such as a supercluster, will cause CMBR photons passing through it to be blueshifted (redshifted) relative to photons reaching us from other directions, causing an anisotropy in the CMBR on the scale of the size of the supercluster (a few degrees). If the entire mass of $2.7 \times 10^{16}\,h^{-1}\,M_\odot$ of the Great

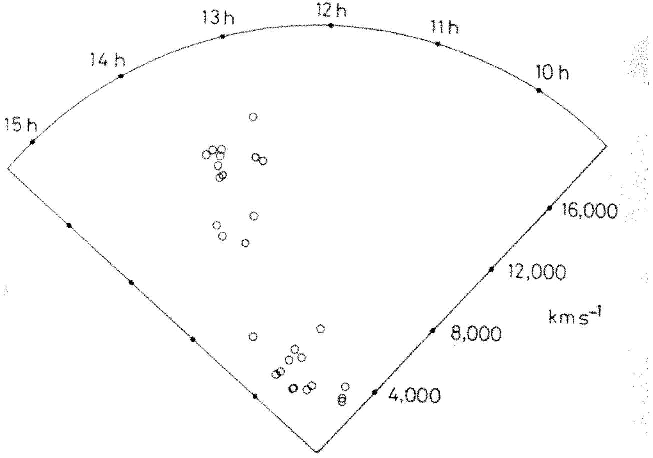

FIG. 3 A wedge diagram of galaxy clusters with known redshifts, showing the position on the sky (right ascension) against mean redshift. The plot clearly shows the existence of two distinct groups of clusters. The nearer group is known as the 'Hydra–Centaurus Supercluster', consisting of three subgroups: (1) the 'Hydra' subgroup at a distance of $\langle v \rangle = 3{,}000$ km s^{-1}, (2) the 'Centaurus' subgroup at $\langle v \rangle = 3{,}200$ km s^{-1}; and (3) the Klemola 27 subgroup at $\langle v \rangle = 4{,}500$ km s^{-1}. The further group, between $10{,}000 < v <$ 16,500 km s^{-1}, is the 'Shapley Concentration', the mean redshift being $\langle v \rangle = 13{,}620$ km s^{-1}. Note the absence of clusters between 5,000 and 10,000 km s^{-1}, and beyond 3,500 km s^{-1} in the range 9 h < RA < 12 h 30 min.

Attractor[1], at a distance of 4,350 km s^{-1}, were confined to a uniform sphere of radius 15 h^{-1} Mpc ($\delta\rho/\rho_0 = 6\Omega_0^{-1}$), it would produce $|\Delta T/T| \approx 2\times10^{-6}$ for $\Omega_0 = 1$. On the other hand, if the Shapley Concentration at 13,600 km s^{-1} were the Great Attractor, and could be represented as a spherical supercluster of mass $2.6\times10^{17}\,h^{-1}\,M_\odot$ within a radius of 20 h^{-1} Mpc ($\delta\rho/\rho_0 = 27\Omega_0^{-1}$), it would lead to a Rees–Sciama effect of the order of $|\Delta T/T| \approx 4\times10^{-5}$. This is close to the observable limits of the Davies *et al.* beam-switching experiment[20], which in its present configuration cannot point so far south in declination.

Both the values of the luminosity and the optical (diameter) dipole of the Shapley Concentration indicate that it could be responsible for $\lesssim$10% of the net acceleration of the Local Group, the rest being due to much nearer galaxies. It would also have a slightly greater dynamical effect on the nearer galaxy concentration, which in turn retains its status as the principal 'Great Attractor' as far as the Local Group is concerned. ☐

ACKNOWLEDGEMENTS. I thank the members of the APM group at Cambridge for scanning the UKST plates, in particular M. J. Irwin, S. J. Maddox and J. Loveday for their APM reduction software. I am grateful to D. Lynden-Bell for advice and encouragement, to J. Loveday for supplying the values of $\langle\Delta^2_{SGP}\rangle$, to M.J. Rees and A.C. Fabian for discussions and to S. Tritton and C. Thoburn for supplying plates at short notice. The author is supported by the Isaac Newton Studentship at the University of Cambridge.

Pre-biotic organic matter from comets and asteroids

Edward Anders

Enrico Fermi Institute and Department of Chemistry, University of Chicago, Chicago, Illinois 60637-1433, USA

SEVERAL authors[1–3] have suggested that comets or carbonaceous asteroids contributed large amounts of organic matter to the primitive Earth, and thus possibly played a vital role in the origin of life. But organic matter cannot survive the extremely high temperatures ($>10^4$ K) reached on impact, which atomize the projectile and break all chemical bonds. Only fragments small enough to be gently decelerated by the atmosphere—principally meteors of 10^{-12}–10^{-6} g—can deliver their organic matter intact[4]. The amount of such 'soft-landed' organic carbon can be estimated from data for the infall rate of meteoritic matter. At present rates, only ~0.006 g cm^{-2} intact organic carbon would accumulate in 10^8 yr, but at the higher rates of $\sim4\times10^9$ yr ago, about 20 g cm^{-2} may have accumulated in the few hundred million years between the last cataclysmic impact and the beginning of life. It may have included some biologically important compounds that did not form by abiotic synthesis on Earth.

Figure 1 shows the present estimates of the meteoritic mass influx on Earth[5], including meteors, meteorites and crater-forming bodies (asteroids and comets). The meteor data[6] cover only the past few decades, but as they agree[7] with noble-metal measurements in deep-sea sediments[5,8] and lunar soils[9], they should be representative of the past $\sim3.6\times10^9$ yr. The cratering curve should be similarly representative, being based in part on crater counts on lunar maria that are 3.3–3.8×10^9 yr old (ref. 10).

Now consider the size ranges in which organic matter can be preserved (shaded areas in Fig. 1). At very small masses, ultraviolet photolysis alters and destroys the organic matter. For the sake of definiteness I set the limit for such destruction at $<10^{-12}$ g. At higher masses, atmospheric friction heats the particle to increasingly higher temperatures. The nominal threshold for boiling of silicates is $>10^{-6}$ g, but it depends strongly on density, velocity, entry angle and fragmentation[6,11]. Well preserved interplanetary dust particles (containing noble gases, nuclear tracks and organic matter) range up to 50 μm in size[11] and as many of these may be fragments of larger aggregates or particles, I adopt 10^{-6} g as the upper limit for survival of organic matter. In the next few intervals, much or all of the mass is lost by ablation[6,11], and any remainder is strongly heated by conduction. Ablation calculations and thermoluminescence data show that pyrolytic temperatures (>600 °C) generally extend <1 mm into the meteorite[12], and thus survival of organic matter—at least for low-velocity objects—becomes possible at larger masses, say 10 g. At still larger masses, atmospheric deceleration becomes progressively less effective, causing increasing destruction in the atmosphere[13] or on impact. A reasonable upper limit is 10^8 g, as meteorites of that mass usually reach the ground with a significant fraction of their cosmic velocity. (Also, the largest stony meteorite showers have masses of only a few tonnes.)

It is useful to estimate the accretion rate not only of organic C but also of total C. The first four lines of Table 1 give such data for the main types of meteoritic material. A few numbers require justification.

For meteors, I use the mean carbon value of ~10% for interplanetary dust particles[14] rather than the 24% reported for comet Halley dust[15], as the latter was measured near the comet nucleus where ices had not yet completely vapourized. This value should also apply to dead comets, which are far more likely to strike the Earth than live comets. (The luminous lifetime of an Earth-crossing short-period comet is typically $\sim10^3$–10^4 revolutions, whereas its dynamical lifetime is $\sim10^7$ revolutions.) For the crater-forming bodies, I assume equal numbers of comets, carbonaceous asteroids and non-carbonaceous asteroids. Several lines of evidence indicate a ratio of ~1:1 for the two asteroid classes (see below), but the fraction of comets is poorly constrained, with estimates[10,16] in the range 10–70%. For meteorites, we assume a carbon content of 1.3%, representing 50% ordinary chondrites (median ~0.1% C) and 50% carbonaceous chondrites (range 0.35–4.8% C). Although the latter constitute only 6% of observed stony meteorite falls, this rarity reflects preferential destruction in the atmosphere owing to their friable nature. Carbonaceous objects seem to account for about one-half of the photographic fireballs[17] with final velocities $\leq$8 km s^{-1}, one-half of the asteroids near the 3:1 Kirkwood gap which are thought to be the principal source of meteorites[18], 13 out of 32 Apollo-Amor asteroids[19], and 3 out of 5 chondritic impactors chemically identified at terrestrial craters[20].

Next, I consider the unmelted material. Meteors pass through the atmosphere intact, but meteorites lose much of their mass by ablation. The ablation loss depends strongly on velocity, mass and crushing strength[13]. I shall use 90% for non-carbonaceous chondrites[21] and 99.4% for carbonaceous chondrites (the latter figure is chosen to reduce the proportion of C-chondrites from 50% to 6%).

Obviously, meteors supply most of the organic carbon. It will not be pristine, having been altered by solar ultraviolet and atmospheric heating, but this could make its chemistry more, rather than less, interesting. Meteorites supply only a negligible fraction ($\sim 2\times10^{-5}$) of the total.

The accretion rate of intact organic C, 3.2×10^{8} g yr^{-1}, would give 3.2×10^{16} g, or 0.006 g cm^{-2}, in 10^{8} yr. This amount is either large or small, depending on the frame of reference: although five times greater than the mass of the marine biosphere, it corresponds to a mean carbon concentration in the oceans of only 2×10^{-5} g l^{-1}. But the true value must be higher, because meteorite infall rates were much higher during the first $\sim 10^{9}$ yr of the Earth's history, when the inner planets swept up left-over planetesimals as well as asteroids and comets scattered by the giant planets. To assess the amount of organic carbon contributed by this 'early intense bombardment', we first consider the origin of the Earth's crustal carbon (1.4×10^{23} g; ref. 22).

Less than 10^{-3} of this carbon can come from meteorite infall at present rates over 4.5×10^{9} yr. Even if we count all meteors in Fig. 1 and integrate the comet-asteroid distribution to $m = 8.7\times10^{20}$ g (one impact of this mass or larger is expected in 4.5×10^{9} yr), the total mass is only 2.1×10^{21} g (including 7.4×10^{19} g meteors). For a bombarding population composed equally of comets, carbonaceous asteroids and non-carbonaceous asteroids, the mean C content is 4.2%, which gives a total carbon accretion of 9×10^{19} g in 4.5×10^{9} yr, or only 7×10^{-4} of the Earth's crustal C.

There is good reason to believe that the remaining C (and N, H) was acquired as a 'late veneer' of carbonaceous material during the final stages of the Earth's accretion[23-25]. Not only C, N and H but also other volatile elements (Tl, Pb, B, In, Bi, Cl, Br, I, Ar and Kr) are present in the Earth's crust in approximately C1-chondrite proportions[23,25]. As these elements differ in volatility and atomic weight, it is unlikely that the observed, flat abundance pattern (Fig. 4 of ref. 25) could have arisen from 'impact volatilization'[26,27]—a popular but dubious concept for the final stages of Earth's accretion. It is more likely to reflect an original nebular condensation pattern that was preserved during formation of the crust. (These elements are incompatible with mantle minerals and would strongly concentrate in the crust during mantle differentiation.) The threshold of ~400 K for carbon condensation as complex organic matter[28] is still recognizable in the asteroid belt, where dark, carbonaceous asteroids become dominant at >2.5 AU (ref. 29). About 4.0×10^{24} g of Cl-chondrite-like material ($6.7\times10^{-4}\ M_\oplus$, or a 3.5-km layer) would suffice to account for the 1.4×10^{23} g carbon at the Earth's surface, and the amounts needed for N and H are rather similar (2.9×10^{-4} and $1.5\times10^{-3}\ M_\oplus$).

Two further lines of evidence indicate an infall of this order. First, the uniform enrichment of noble metals (Pd, Re, Os, Ir, Au) in the upper mantle, at $(7.32\pm0.99)\times10^{-3}$ Cl-chondrite abundances[30], apparently implies that highly oxidized, chondritic material fell on the Earth after core formation, leaving its siderophile elements stranded[30,31]. One mantle xenolith showing such enrichment, a sheared garnet lherzolite of particularly primitive composition[32], comes from >150 km depth and so the 'megaregolith' from the late bombardment presumbly extends to at least this depth. This would imply $>5\times10^{-4}\ M_\oplus$ of chondritic material in the upper mantle, which is remarkably consistent with the above values for C, N, H and noble metals (overall mean = $(7.4\pm2.7)\times10^{-4}\ M_\oplus$). Second, the size and age distribution of impact basins on the Moon indicates that the Earth accreted 1.3×10^{-4}-$3.8\times10^{-2}\ M_\oplus$ of material between 3.8 and 4.5 Gyr ago[33]. Some authors have postulated a very large influx of cometary bodies from the region of the outer planets[34], but as only one of the last nine large bodies to strike the Moon[35,36] resembled C-chondrites[30], only part of the bombarding population was carbonaceous.

Although this late accretional component was $\sim 10^{3}$ times greater than the total meteoritic influx at present rates, it probably yielded a smaller proportion of intact organic matter. Like today, the most efficient vehicle for delivery of organic matter would be meteors in the range 10^{-12}-10^{-6} g (or higher if the atmosphere was denser). The meteor fraction probably was at least as large as the present one, that is, ~20% of the total (Table 1), as the disintegration rate of comets should have been similar and the collision rate in the asteroid belt was higher[37]. Much of the soft-landed organic matter would be destroyed or degraded, however, first by the high temperatures of the crust and atmosphere during the most intense stages of the bombardment, then by recurrent vapourization of the ocean and by burial. Material cycled through the >150-km megaregolith would be pyrolysed to elemental C and small molecules such as CO and CH_4, so only organics accumulated in the ocean and in the last few kilometres of the regolith would escape serious degradation.

A reasonable guess—good to perhaps a factor of 3-5—is that only ~1% of the Earth's surface carbon ($\sim 1.4\times10^{21}$ g) accreted under conditions permitting survival of organic carbon. (One per cent of the accretable material ($\sim 5\times10^{22}$ g) would suffice to evaporate the ocean and to deposit several kilometres of ejecta, so accumulation of organic matter probably began only during the last few per cent of the accretion process, but at first with very low efficiency.) If the fraction of meteors, and hence intact organic carbon, was the same as in the most recent infall, that is ~8% (Table 1), this corresponds to 1.1×10^{20} g organic C, or 10^{2} times the total infall in 4.5×10^{9} yr at present rates. This amount is equivalent to 21 g cm^{2} or an oceanic carbon concentration of 0.08 g l^{-1}.

Even 1.1×10^{20} g C is comparable to the 10^{20}-10^{21} g of HCN and HCHO expected from Miller-Urey reactions in the Earth's atmosphere ($H_2/CO_2 = 1$) over 600 Myr (ref. 38). Amounts aside, meteoritic and cometary organic matter may well have

TABLE 1 Accretion rates on Earth

Sources	Mass range (g)	Mass accretion rate (Gg yr^{-1})	Carbon content (%)	Carbon accretion rate (Gg yr^{-1})
Total meteoritic matter	10^{-14}-10^{18}	78	—	4.2
Meteors	10^{-14}-10^{2}	16	10	1.6
Meteorites*	10^{1}-10^{8}	0.058	1.3	7.6×10^{-4}
Crater-forming bodies†	10^{8}-10^{18}	62	4.2	2.6
Unmelted material, contributing organic matter				
Meteors	10^{-12}-10^{-6}	3.2	10	0.32
Meteorites, noncarbonaceous‡	10^{1}-10^{8}	2.9×10^{-3}	0.1	2.9×10^{-6}
Meteorites, carbonaceous§	10^{1}-10^{8}	1.9×10^{-4}	2.5	4.7×10^{-6}

* Assumed pre-atmospheric abundances: 50% carbonaceous chondrites (2.5% C) and 50% noncarbonaceous meteorites (0.1% C).

† Assuming equal mass fractions of dead comets (10% C), carbonaceous asteroids (2.5% C), and noncarbonaceous asteroids (0.1% C).

‡ Assumed ablation loss 90%.

§ Assumed ablation loss 99.4%, to yield observed fraction of 6% carbonaceous chondrites among stony meteorites.

played an important role in pre-biotic evolution, as it formed by different processes (ion-molecule and photochemical reactions in interstellar clouds, grain catalysis in the solar nebula, aqueous chemistry in asteroids) and thus contains a different mix of compounds, including N-heterocyclics, aromatics, amphiphilic compounds, porphyrin-like pigments, and so on, that are not readily made by Miller-Urey reactions[28,39-41].

There are several uncertainties in this estimate: the fraction of carbon-rich objects in the final stages of bombardment, the fraction disintegrated to meteor-sized dust, the onset of safe conditions on Earth, the pressure of the atmosphere, and the net yield of organics from large, friable bodies. A higher pressure would extend aerobraking to higher masses[42], thus raising the soft-landed fraction in Fig. 1. Survival of dust from large, friable bodies would have the same effect. Öpik[43] has calculated that aerodynamic pressure would cause large stony meteorites to disintegrate into a flat sheet of dust and rubble, which would be decelerated to less than crater-forming velocities at masses $\leq 10^{12}$ g. Thomas *et al.*[42] have suggested that part of this debris might be decelerated so gently as to permit survival of organic matter.

At first sight, the empirical data are permissive, or even encouraging. No unmelted material has been found from the Tunguska object, but this may merely reflect its inconspicuous nature and lack of ferromagnetism. Very large amounts of two non-protein amino acids (AIB and ISOVAL) have been reported +0.3 m and −0.5 m from the Cretaceous/Tertiary (K/T) boundary at Stevns Klint, and have been attributed to soft-landed material from a comet[44]. However, these results are in sharp conflict with measurements of Xe in 9 K/T boundary samples from 3 sites, including 6 from Stevns Klint[45,46]. The AIB/Ir ratio is about five times the value in the Murchison C2-chondrite and implies essentially complete survival of the impactor, whereas the Xe/Ir values range from $\leq 6\times10^{-3}$ to 2×10^{-5} of the C-chondrite value, and imply essentially complete destruction. Differences in temperature sensitivity of AIB and Xe cannot explain this discrepancy, as amino acids are far more readily lost than is Xe (seconds at 1,000 K against hours at 1,200-1,500 K), and neither can differences in composition. Comets are ~10-fold enriched in C and N and hence perhaps in amino acids, but they are not likely to be significantly depleted in Ir, as judged from the C-chondrite-like pattern of the micrometeorite component in lunar soils[9] and from the relatively normal abundances of cosmochemically similar elements in comet Halley[15] (Fe = 0.62, Ni = 0.87, Ca = 1.10 of C1-chondrite values). Xenon actually is more abundant in IDPs[47] than in C1 chondrites, by a factor of about ten.

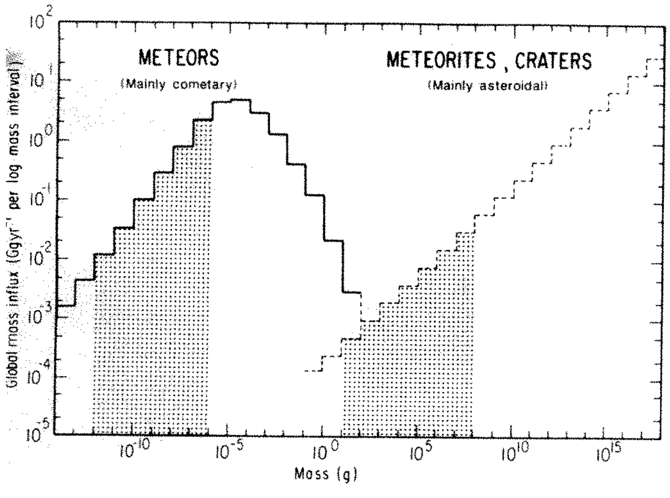

FIG. 1 Infall rate of meteoritic matter on Earth (adapted from ref. 5). Intervals where organic matter can survive passage through atmosphere are shaded. The curve on the right is based on the relation[5] $N=0.54\ r^{-2.1}$ (N = number of impacts per Myr, r = radius in km), for an assumed density of 3 g cm^{-3}. The corresponding mass accretion rate (Gg yr^{-1}) between r_1 and r_2 is $15.83\ (r_2^{0.9}-r_1^{0.9})$.

Furthermore, there are theoretical arguments against survival of unmelted material from comets the size of the K/T impactor (~10^{18} g). During atmospheric passage, such a body would lose only ~10^{-3} of its momentum or mass, unless it had a very small entry angle or very irregular (non-equant) shape[48]. Moreover, the 'ground track' a of the comet's atmospheric trajectory is $h/\tan\alpha$, where h is the altitude where significant fragmentation begins and α is the elevation angle. If $h = 50$ km (ref. 49) and $\alpha \geq 20°$, then a is only ≤ 137 km, much smaller than the ~1,200-km radius of the fireball. Any debris spalled from the comet during atmospheric passage will be engulfed by the fireball and destroyed.

Survival of organic matter against this destruction mechanism becomes possible when the fireball radius is shorter than the ground track, that is at masses $<10^{15}$ g. If a significant fraction of the spalled-off dust is gently decelerated[42] without melting or pyrolysis, then friable bodies of 10^8-10^{12} g may contribute some organic matter. However, at present it seems that the best vehicle for carrying organic matter to Earth is cometary dust formed before atmospheric entry. □

Determination of 4-connected framework crystal structures by simulated annealing

M. W. Deem & J. M. Newsam

Exxon Research and Engineering Company, Route 22 East, Annandale, New Jersey, USA

THE initial derivation of atomic-scale models of the 4-connected framework crystal structures of zeolites and related materials is generally difficult. Interpretation of powder X-ray diffraction data to yield a unit cell and some symmetry information is often straightforward. Chemical analyses and sorption experiments indicate the number of framework tetrahedra, n_T, present in the unit cell (T represents the framework tetrahedral species, such as Si or Al) and the approximate pore dimensions. However, because synthetic zeolites are almost invariably microcrystalline, the possibilities for structure solution by conventional diffraction methods are limited, and framework structure determinations have traditionally relied heavily on the building of physical models. We describe here an alternative approach, in which approximate T-atom coordinates are derived from the unit-cell size and symmetry, and the value of n_T from computer modelling. An initially arbitrary T-atom configuration is optimized with respect to a 'cost function' based on the T–T distances, T–T–T angles and number of first-neighbour T-atoms, by simulated annealing using Monte Carlo methods. The potential of the method for structural determinations in both two dimensions (for structural projections) and three dimensions are illustrated by results obtained for a hexagonal cell of space group $P6/mmm$ and dimensions $a = 18.4$ Å and $c = 7.5$ Å, and by determination of the previously unknown structure of lithium gallosilicate.

A large proportion of the ~65 known zeolite framework structure types[1] were solved based on an initial determination of the 4-connected T-atom framework by, for example, physical model building[2], by consideration of direct derivatives of known structures[3], or by interpretation of electron microscopy and diffraction data[4,5]. Oxygen atoms can be added at the midpoints of each of the T–T vectors, and the T- and O-atom coordinates then optimized readily by distance least-squares (DLS) based on established constraints on the T–O, O–O and T–T distances[6,7]. The problem of structure solution reduces to one of defining approximate T-atom coordinates. The present approach describes the reasonableness of a given arrangment of the required number of T-atoms in the known unit cell in terms of a cost or 'energy' function and uses simulated annealing to adjust the T-atom coordinates to minimize that energy.

We define the total energy of a given T-atom configuration as the sum over the unique T-atoms of terms based on the T–T distances, T–T–T angles, the number, N_1, of first neighbours, and (when T-atoms are possibly located on symmetry elements) the number of symmetry operations that reproduce the original T-atom (Fig. 1). The forms of the energy as a function of the T–T distances and of the T–T–T angles are derived from histograms of observed data from a representative number of known zeolite structure types. The neighbour term is calculated from the number of T-atoms within a defined shell. The merging contribution is calculated from the distance between symmetry-related T-atoms found at less than a defined separation; merged atoms are excluded from the calculations of the other energy terms. Merging is permitted provided the total number of T-atoms per unit cell is $\geq n_T$. Appropriate relative weights of the four types of constraint were derived largely by trial and error, with the parameters being treated as tunable in complicated cases. Appropriate adjustment of these various terms (particularly the neighbour term) permits the same method to be applied to other coordination environments such as those that occur, for example, in mixed octahedral-tetrahedral framework structures.

Optimization of the coordinates of the unique T-atoms (the full unit-cell T-atom complement is generated by application of the space-group operators) to minimize the calculated energy sum is achieved by Monte Carlo methods using simulated annealing[8,9] based on an initially random configuration. During annealing low-energy, 4-connected configurations generated are stored for further evaluation (typically, 2-20 are produced in each run). Simple representations (projections down the three principal crystallographic directions) of the full unit-cell contents for each of the saved models are examined visually, followed, where appropriate, by further molecular graphics analyses, or by addition of framework oxygen atoms and DLS optimization and/or simulation of the powder-X-ray diffraction pattern(s). A typical run for a three-dimensional case (see below) with $n_{\text{unique}} = 2$ unique T-sites, 24 symmetry operators and $n_T = 36$ consumes ~60 min CPU time on a VAX8350, or ~60 s on a Cray XMP/14 se.

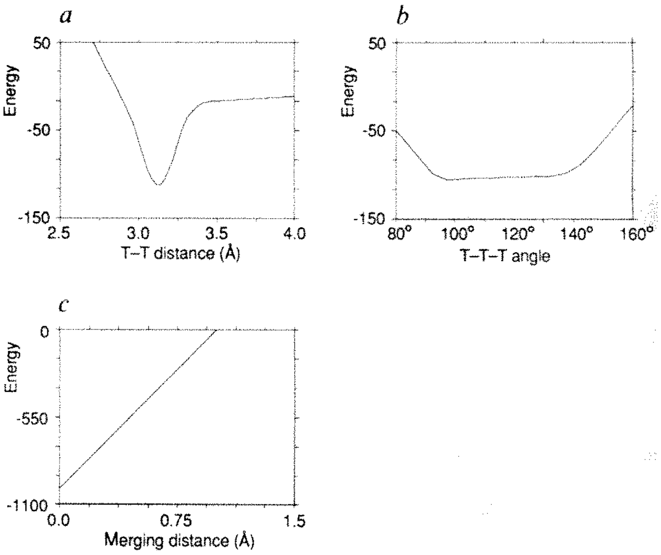

FIG. 1 Energy as a function of the T–T distance (*a*) and the T–T–T angle (*b*) used in the simulation procedure (calculated as smoothing spline fits to Boltzman equilibrium interpretations of histogrammed data taken from 32 representative zeolite crystal structures). Only the central portions are shown, the energy curves extrapolating linearly to energies of 1,000.0 and 0.0 at T–T distances of 0.0 and 5.0 Å, and to energies of 5,000.0 and 0.0 at T–T–T angles of 0.0 and 180° respectively. (*c*) The contribution to the energy sum for the merging of two symmetry-related atoms; merging is only permitted when the two atoms are at less than a defined minimum distance. The contribution to the energy sum from the coordination term is typically set to 1,000.0, 800.0, 600.0, 300.0, 0.0, 300.0, 600.0 for 0, 1, 2, 3, 4, 5 and 6 T-atoms within the defined first-neighbour radius (typically 3.7 Å) respectively.

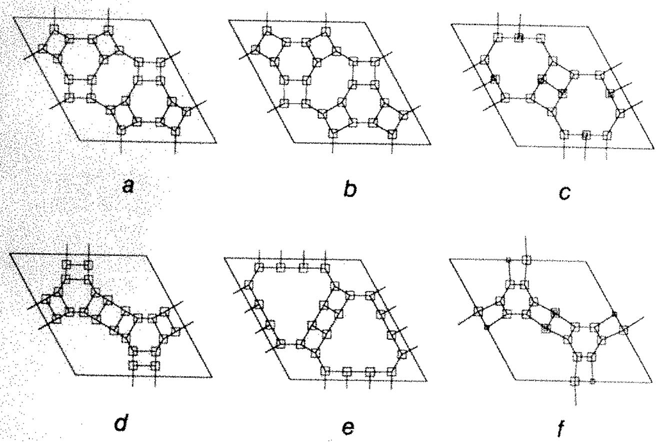

FIG. 2 The projection of the T-atom configuration in zeolite L (*a*) compared with two-dimensional modelling results (*b*–*f*) based on a hexagonal plane cell, *p6mm*, with $a = 18.4$ Å (see text). Smaller squares indicate degenerate atoms.

In the known zeolite framework structure types[1], the main pores generally run parallel to a unit-cell axis, and in projection the T-atoms are reasonably dispersed and usually 3-connected. The present methods were, therefore, developed initially based on the (simpler) two-dimensional, projection case. The constraints on both T–T distances and T–T–T angles were relaxed substantially to enable proper treatment of T–T linkages oblique to the projection direction. Results for a plane cell with *p6mm* symmetry (with 12 symmetry operators) and $a = 18.4$ Å, for $n_{\mathrm{unique}} = 2$ and $n_{\mathrm{T}} = 24$, and for $n_{\mathrm{unique}} = 2$ and $n_{\mathrm{T}} = 18$, are shown in Fig. 2. A single run with $n_{\mathrm{unique}} = 2$ and $n_{\mathrm{T}} = 24$ yielded the *ltl* net (ref. 10) (Fig. 2*b*) expected for projections of the LTL and MAZ frameworks[1], and nets labelled *tsv* (Fig. 2*d*) and *twy* (Fig. 2*e*) by Smith[10] (the projections of the three-dimensional 4-connected nets numbered 313 (ref. 11) or 81(2) (ref. 12), and 318 (ref. 11), respectively). The two-dimensional nets labelled *eoo* (ref. 10) (Fig. 2*f*)(the projection of the 81(1) or 520 net (ref. 13) adopted by the 18-ring aluminophosphates VPI-5 (ref. 14) and $ALPO_4$-54 (ref. 13) and *tfn* (ref. 10) (Fig. 2*c*) were produced in a run based on $n_{\mathrm{unique}} = 2$ and $n_{\mathrm{T}} = 18$. Similarly successful results (in a series of possible hexagonal plane symmetries) were obtained for a smaller cell with $a = 13.3$ Å that is typical of materials in the ABC-6 family of zeolites[15]. The projection approximation, however, does not converge successfully in cases such as the SOD-framework[1], where connected and nonconnected vertices have, in projection, similar separations.

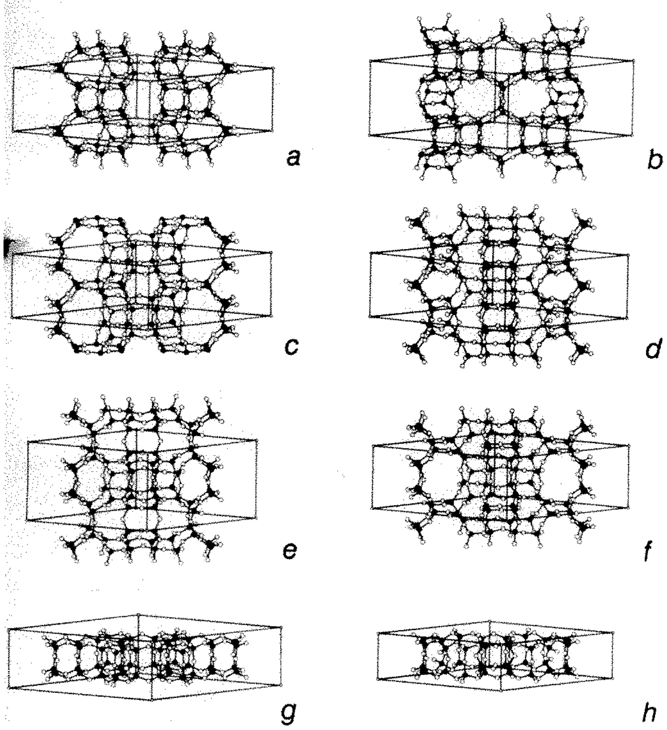

FIG. 3 Ball and stick representations of the eight distinct structure types produced in three-dimensions based on a hexagonal unit cell, *P6/mmm*, with $a = 18.4$ Å, $c = 7.5$ Å, $n_{\mathrm{unique}} = 2$ and $n_{\mathrm{T}} = 36$ that is observed for zeolite L (see text). The structures are shown following addition of the framework oxygen atoms and optimization of the atomic coordinates and the unit-cell dimensions by conventional distance least squares[6,7] (T-atoms, solid; O-atoms, open).

The full three-dimensional case is of greater utility but involves a larger number of independent variables. Annealing parameters that have been adjusted to facilitate convergence include the temperature decrement between successive cooling stages (generally chosen based on the evolution with temperature of the system specific heat[8]), and the temperature dependence of the maximum T-atom displacement in the Monte Carlo jiggle step. Typical results are illustrated in Fig. 3 for a hexagonal cell with *P6/mmm* symmetry (24 symmetry operators), $a = 18.4$ Å, $c = 7.5$ Å, and with $n_{\mathrm{unique}} = 2$ and $n_{\mathrm{T}} = 36$ that is observed for zeolite L. A total of ten different runs generated, in aggregate but with much duplication, the LTL-framework[1] (Fig. 3*a*), the hypothetical framework initially proposed for zeolite omega[16] (Fig. 3*c*), frameworks corresponding to nets numbered 313 (Fig. 3*b*), 318 (Fig. 3*d*) and 315 (Fig. 3*e*) described previously[11], a related framework with a circuit symbol $(4^3 6^3)_1(4^3 6^3)_2$ (Fig. 3*f*), and two sheet structures (Fig. 3*g* that has $n_{\mathrm{T}} = 48$, and Fig. 3*h*) that were observed with relatively high energies only at high simulation temperatures. These topologies correspond in each case to one of the two-dimensional nets deduced in the projection approximation (Figs 3*a*, 3*c* and 3*g* correspond to Fig. 2*b*; Fig. 3*b* to Fig. 2*f*, Figs 3*d* and 3*f* to Fig. 2*d*; Figs 3*e* and 3*h* to Fig. 2*e*). An example of an apparently more constrained system is provided by the high silica, 10-ring zeolite Theta-1 for which a single run (that consumed 15 min Cray XMP/14 se CPU time) based on the orthorhombic space group symmetry $Cmc2_1$, with $a = 13.8$ Å, $b = 17.4$ Å, $c = 5.0$ Å, $n_{\mathrm{unique}} = 4$ and $n_{\mathrm{T}} = 24$ converged to a single 4-connected topology identical to that described for the TON-framework in 1984[17].

Analysis of data for a condensed lithium gallosilicate that was recently described to be orthorhombic, space group *Pnam* or $Pna2_1$, with $a = 10.04$ Å, $b = 6.63$ Å, $c = 4.96$ Å (ref. 18) illustrates the solution of an unknown structure by the present method. Two runs based on this unit cell, space group $Pna2_1$, $n_{\mathrm{unique}} = 2$ and $n_{\mathrm{T}} = 8$, produced some 20 trial structures, which on inspection were found to represent different settings of three distinct 4-connected topologies. The correct model (Fig. 4) was identified by comparing the observed powder X-ray diffraction pattern with those simulated on the basis of the three models

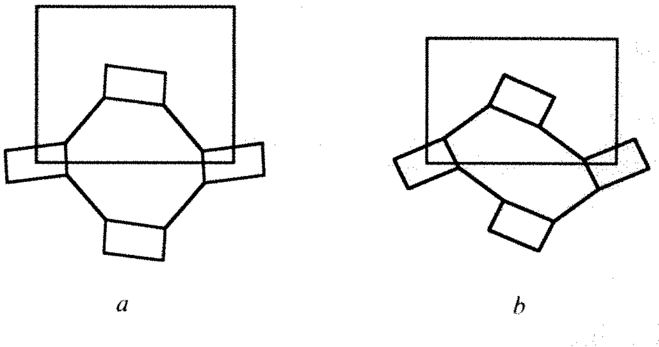

FIG. 4 The [001] projections of the framework structures of gallosilicate zeolite Li-A(BW) (*a*) compared with the DLS-optimized framework structure of its calcination product (*b*) solved by the present method.

with oxygen atoms entered (approximately) at the midpoints of the T-T vectors. This structure proves to be isotopological with gallosilicate zeolite Li-A(BW) of which it is a calcination product[18]. Removal of the sorbed water results in gross readjustment of the 8-ring channel, a 20% reduction in the length of the *b*-axis (Fig. 4), and a powder X-ray diffraction pattern that bears no resemblance to that of the parent. Although no sorption capacity for water was noted in this material[18], reversion to the parent hydrated structure may occur over extended periods under suitable water vapour pressures.

The present algorithms apparently work well for small numbers of unique T-atoms, $n_{\text{unique}} < {\sim}6$ (which encompasses >85% of the known zeolite structure types in their highest possible symmetries[1]), where a small number of passes through the program generally yields the sought solution(s). For larger numbers of independent T-atoms, especially when merging is required, many 4-connected topologies are produced. The present energy function is apparently not yet sufficiently restrictive in these more complicated cases. By evaluating results for a larger number of known materials, however, it is hoped to further improve the constraint functions and the parameters controlling passage through the simulated annealing process. Although certainly not guaranteed to work in all cases, these procedures provide a new approach to the difficult process of zeolite structure solution, and a rapid means of extending studies of hypothetical 4-connected nets. ☐

Strontium, neodymium and lead isotope constraints on near-ridge seamount production beneath the South Atlantic

Pat Castillo*‡ & Rodey Batiza†

STUDIES[1-7] of seamounts near the East Pacific Rise (EPR) have shown that, although most seamount lavas are petrographically and chemically identical to mid-ocean-ridge basalt, they are chemically and isotopically more diverse than those erupted on the rise axis. They are also generally more primitive (higher MgO content) and, in some cases, more depleted in incompatible elements than the axial basalts. This indicates that although near-ridge seamounts and the EPR share a common mantle source, there must be significant differences in their magma-supply processes. Seamounts are probably built by small batches of melt that rise rapidly to the surface, preserving evidence of heterogeneity in the mantle source region. By contrast, the processes of melting and melt segregation, storage and extrusion along the fast-spreading (9–13 cm yr^{-1}) EPR are more efficient in mixing and homogenizing basalt compositions[1-7]. Here we show that the relationship of strontium, neodymium and lead isotope data between seamounts in the South Atlantic and the nearby axis of the slow-spreading Mid-Atlantic Ridge (MAR) is similar to that seen in the Pacific. This indicates that the processes leading to formation of near-ridge seamounts are similar at a wide range of spreading rates. Differences in the specific isotope signatures of lavas from near-ridge seamounts and axes of the EPR and MAR reflect regional differences in the upper-mantle source of mid-ocean-ridge basalts.

The new Sr, Nd and Pb isotope data presented here (Table 1) are mostly from glassy basalts that were dredged from seamounts near the MAR during cruise RC 2802 (RV *Conrad*) in 1987[8,9] (Fig. 1). For comparison, we also present a new graphical representation of isotope data for fresh glassy basalts dredged at an average spacing of ~7 km along the MAR from the Rio Grande (25°40′ S) to the Moore (26°30′ S) fracture zones. This segment of the MAR at 26° S is spreading slowly (3-4 cm yr^{-1}) and is far from active hotspot volcanism. Indeed, all lavas from the MAR at 26° S and near-ridge seamounts are 'normal' mid-ocean-ridge basalts (MORBs) in terms of major and incompatible element contents[8,9]. As in the EPR, seamount basalts are systematically richer in MgO and more depleted in TiO_2 contents than most of the axial lavas. Major-element data indicate that the seamount basalts and some high-MgO axial lavas from near the fracture zones and the axial high (Fig. 1) were produced by smaller extents of partial melting at slightly higher pressure than most of the axial lavas[8,9].

Seamounts basalts have more variable $^{87}Sr/^{86}Sr$ and $^{143}Nd/^{144}Nd$ values than the axial lavas in the South Atlantic (Table 1 and Fig. 2*a*). Moreover, Sr isotopic ratios are generally higher and Nd isotopic ratios are lower for seamount basalts than for axial lavas. For example, samples 9 and 10, which are from one seamount, range from 0.70260 to 0.70350 in $^{87}Sr/^{86}Sr$ and from 0.51297 to 0.51314 in $^{143}Nd/^{144}Nd$ values. Sr and Nd isotopic ratios of samples 5, 6 and 7, also from a single seamount and related cones, are less variable but these ratios still are more diverse than those of axial lavas from the MAR nearby that vary from only 0.70247 to 0.70259 in $^{87}Sr/^{86}Sr$ and from 0.51308 to 0.51314 in $^{143}Nd/^{144}Nd$ values (P. C., unpublished data).

Except for sample 9, $^{206}Pb/^{204}Pb$ values of seamount basalts (18.21-18.33) are well within the range of the axial lavas (18.16–18.40) (Table 1 and Fig. 2*b*). In turn, the Pb isotope signature of the axial lavas is very similar to that of other normal-MORBs from the 22° S to 31° S segment of the MAR[10]. Seamount basalts, however, have distinctly more variable and systematically higher $^{208}Pb/^{204}Pb$ and, to a lesser extent, $^{207}Pb/^{204}Pb$, for given $^{206}Pb/^{204}Pb$ values than the axial lavas (37.86-38.17 against 37.73-38.07, and 15.47-15.55 against 15.48-15.53, respectively). Sample 9 has high $^{207}Pb/^{204}Pb$ (15.66) but approximately normal $^{208}Pb/^{204}Pb$ (38.48) for a given $^{206}Pb/^{204}Pb$ value relative to axial lavas (Fig. 2*b*).

Sr isotopic ratios are fractionation corrected to $^{86}Sr/^{88}Sr=0\ 1194$ and normalized to $^{87}Sr/^{86}Sr=0\ 710265$ for NBS 987, Nd isotopic ratios are fractionation corrected to $^{146}NdO/^{144}NdO=0\ 72225$ ($^{146}Nd/^{144}Nd=0\ 7219$) and are reported relative to $^{143}Nd/^{144}Nd=0\ 511860$ for the La Jolla Standard Isotopic composition of Pb are corrected for mass fractionation based on average measured values for NBS 981 using the values given by Catanzaro *et al*[30] All analyses are done on fresh glasses except for 3 samples (indicated by wr) which are done on leached whole-rock powders Sample 9dup is an analysis on a different glass piece of sample 9 Numbers in parentheses are in-run analytical precisions and refer to the last significant digits, in-run precision for Sr isotope measurements <10

These results indicate that despite large differences in spreading rate, both the Atlantic and Pacific display similar axis-seamount isotope systematics, seamounts are more diverse isotopically than axial lavas As the abundances, morphology, and major-element contents of MAR near-axis seamounts are also similar to their Pacific counterparts[8 9], it seems likely that near-axis seamounts are produced by similar processes operating at a wide range of spreading rates Because of the gross petrological similarity of lavas from seamounts and nearby axis, the close proximity of seamounts to the axis, and because the zone of mantle upwelling is thought to be ~100 km wide[11,12], it is very clear that axial and seamount melts tap the same mantle source However, the systematic difference between axial and seamount lavas in major elements, trace elements and isotopes indicates that this common source is tapped in different ways and/or the melt migration and/or the storage history of seamount magmas and axial magmas are different

As already mentioned, the petrological diversity but generally high MgO contents of near-ridge seamount lavas indicate that seamounts tap relatively small volumes of mantle, which rise quickly without extensive modifications[1-7] In addition, seamount magmas may be the result of smaller extents of partial melting, in which case magmas may contain high proportions of more enriched, more easily melted components of the upper mantle[1,5,12] than axial lavas By contrast, axial magmas may be mixed and homogenized during melt segregation, melt migration or storage in crustal magma chambers

Despite the similarity in axis-seamount systematics in the Atlantic and Pacific there are also significant differences For example, Atlantic near-ridge seamounts show much more variability in $^{87}Sr/^{86}Sr$ than do the Pacific ones (Fig 2*a*) Atlantic seamounts exhibit smaller ranges of $^{143}Nd/^{144}Nd$ and $^{206}Pb/^{204}Pb$ variation than Pacific ones, but this could be due to the small data base for Atlantic near-ridge seamounts Note also that Atlantic seamount samples are all normal MORBs whereas in the Pacific, most of the high $^{87}Sr/^{86}Sr$ and low $^{143}Nd/^{144}Nd$ samples are alkali basalts and their differentiates[7] The reason for this is not entirely clear, but it could be due to differences in the depth of origin or age of eruption of Atlantic and Pacific near-axis seamounts Alternatively, the geochemical characteristics beneath the South Atlantic and the Pacific might be different[13]

Another notable feature of the data is that except for some lavas from the Lamont seamount chain in the Pacific[6], Atlantic near-axis seamounts have lower mean $^{206}Pb/^{204}Pb$ than Pacific ones (Fig 2*b*) The Lamont samples, however, have low $^{87}Sr/^{86}Sr$, whereas the low $^{206}Pb/^{204}Pb$ Atlantic samples have high $^{87}Sr/^{86}Sr$ (Fig 3*b*) The overall pattern of lower $^{206}Pb/^{204}Pb$ and lower $^{143}Nd/^{144}Nd$, but higher $^{207}Pb/^{204}Pb$ and $^{208}Pb/^{204}Pb$ for a given $^{206}Pb/^{204}Pb$ of Atlantic seamounts relative to Pacific ones (Figs 2*b*, 3*a*) is apparently paralleled by a similar isotope pattern at the respective ridge axes The MAR in the South Atlantic has a lower $^{206}Pb/^{204}Pb$ than the EPR (Fig 2*b*) Like-

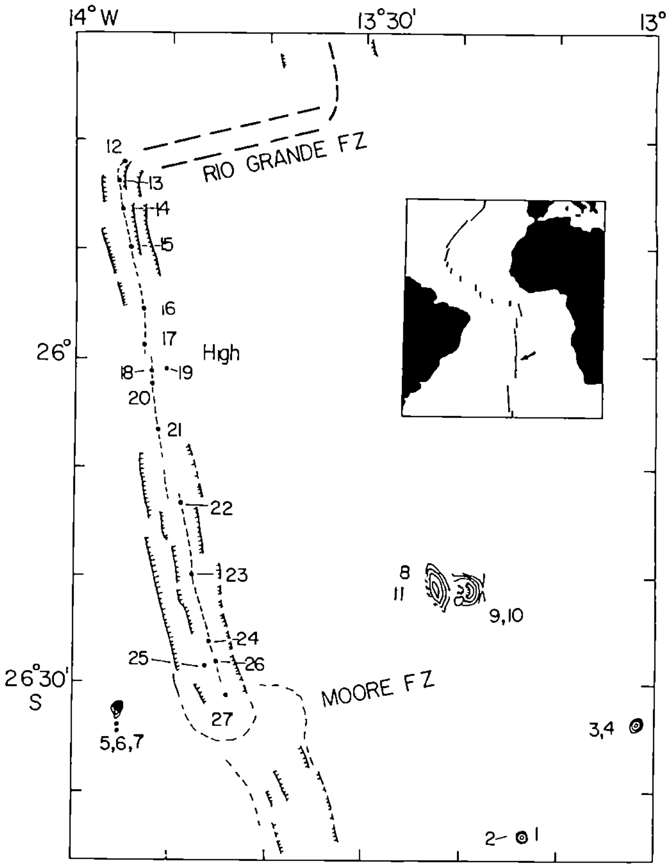

FIG 1 Schematic map of the Mid-Atlantic Ridge between the Rio-Grande and Moore fracture zones, showing dredges on near-ridge seamounts (1-11), along the MAR axis (12-18, 20-24, 26, 27) and slightly off-axis (19, 25) (from ref 8) The ridge axis is elevated near the centre of the segment at ~26° S as indicated

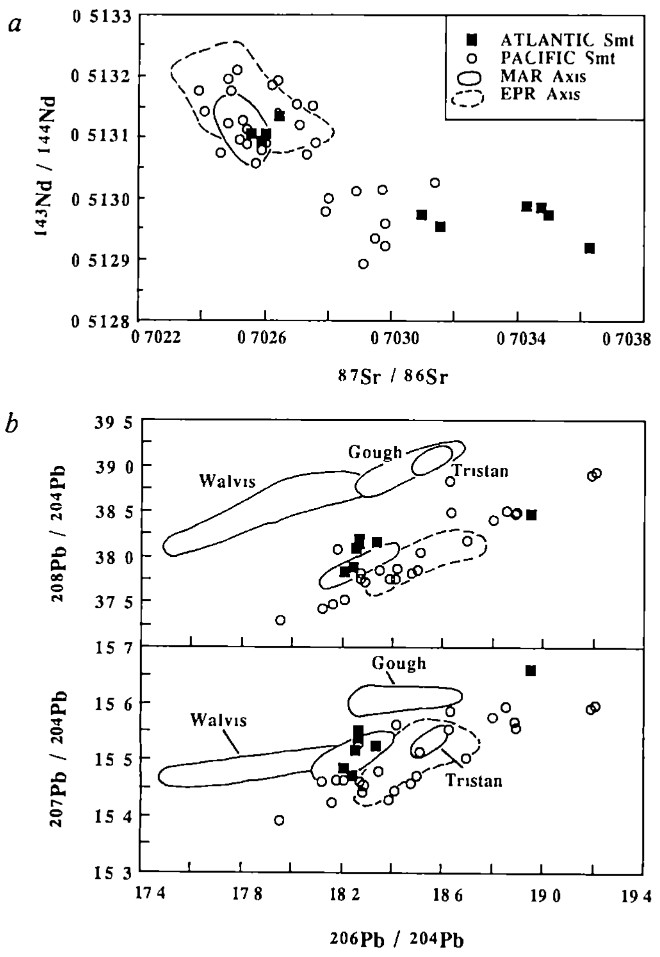

FIG 2 *a*, Plot of ^{143}Nd/^{144}Nd against ^{87}Sr/^{86}Sr for lavas from near-ridge seamounts in the Atlantic and Pacific Isotope data for axial lavas shown for reference are restricted to those segments of the MAR and EPR that are adjacent to the seamounts These isotope data are from the MAR between 25° 40′ and 26° 30′ S (representative samples from dredges 12-27 in Fig 1) and from the EPR between 8° to 22° N latitude *b*, plots of ^{208}Pb/^{204}Pb and ^{207}Pb/^{204}Pb against ^{206}Pb/^{204}Pb for the samples shown in *a* Symbols and reference fields as in *a* (Pb isotope data for an axial lava from the MAR at 26° 00′ S reported by Hanan and Schilling[10] (EN063 12D-5g) plot inside the field for MAR axis) Note that although almost all lavas from near-ridge seamounts and the ridge axis in the south Atlantic have similar ^{206}Pb/^{204}Pb, seamount basalts have higher ^{208}Pb/^{204}Pb and ^{207}Pb/^{204}Pb than axial lavas This Pb isotopic signature is a common feature of lavas from the Tristan da Cunha and Gough hot spots and their apparent trace, the Walvis Ridge, further to the south Data from near-ridge seamounts in the Pacific with lowest ^{206}Pb/^{204}Pb values are from the Lamont group of seamounts[6] Despite the fewer number of available samples from the South Atlantic, near-ridge seamounts clearly are more isotopically heterogeneous than axial lavas

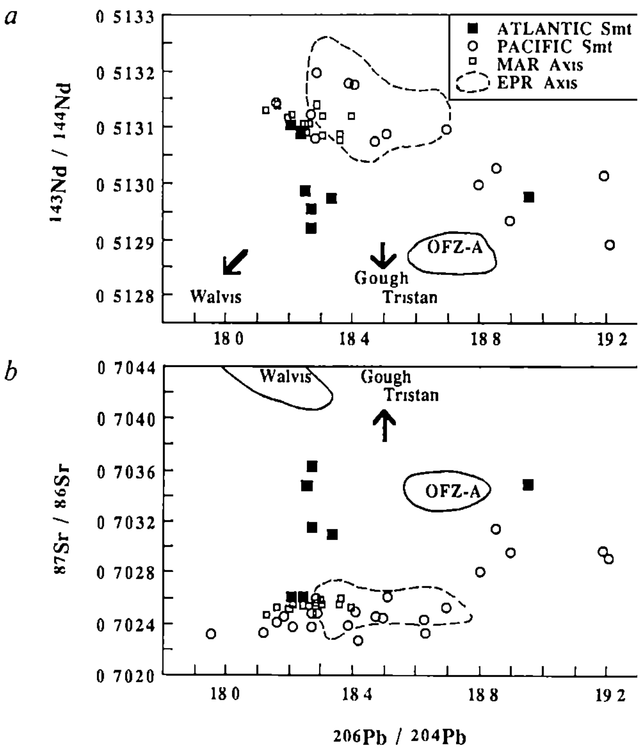

FIG 3 Plots of ^{143}Nd/^{144}Nd against ^{206}Pb/^{204}Pb (*a*) and ^{87}Sr/^{86}Sr against ^{206}Pb/^{204}Pb (*b*) for lavas from near-ridge seamounts in the Atlantic and Pacific Axial lavas from the MAR at 26° S generally have lower mean values of ^{206}Pb/^{204}Pb and lower mean values of ^{143}Nd/^{144}Nd but higher mean values of ^{207}Pb/^{204}Pb and ^{208}Pb/^{204}Pb for given ^{206}Pb/^{204}Pb than axial lavas from the EPR between 8°-22° N These regional isotope differences generally are more pronounced in the isotopic signature of lavas from near-ridge seamounts Nd isotopic ratios of the Lamont seamount basalts are not available, nevertheless, the fairly good negative correlation between Nd and Sr isotopic ratios of other seamounts near the EPR[5,7] indicate that these lavas also have lower ^{143}Nd/^{144}Nd for given ^{206}Pb/^{204}Pb ratios than Atlantic seamount and axial lavas Fields for the Tristan da Cunha, Gough, Walvis Ridge, and 'type A' Oceanographer Fracture Zone lavas[13] are shown for reference Note that all near-ridge seamount and axial isotope data can be enclosed by a single large triangle (not shown) in these two diagrams

wise, the MAR in the South Atlantic has a lower mean ^{143}Nd/^{144}Nd but higher mean ^{207}Pb/^{204}Pb and ^{208}Pb/^{204}Pb than the EPR (Fig 2*b*) These observations are consistent with the notion of a similar mantle source for both axial and seamount magmas

With the exception of some samples from near the Oceanographer Fracture Zone[14] and near the Equator[15], the MAR in the North Atlantic exhibits an isotope pattern different from that in the South Atlantic[10,13] For example, North Atlantic axial MORBs far from hotspots generally have similar ^{206}Pb/^{204}Pb and higher ^{143}Nd/^{144}Nd than the EPR axial lavas[16,17] These apparent differences between the MAR in the North and South Atlantic may be due to regional differences in the mantle characteristics[13], but a possible plume contribution in the South Atlantic[10] is difficult to rule out

The comparison between the South MAR and EPR indicates that near-axis seamount lavas tend to magnify isotope differences that are present but more subdued in axial lavas In the southern MAR, our new data confirm the presence of at least three mantle components as proposed by Hanan *et al*[10] Two of these are also present at the EPR and the third is a component enriched in the Tristan-Gough-Discovery hotspots (Fig 3*a*,*b*) The presence of this component in the near-ridge seamount and in the MAR axial lavas is difficult to explain The large geographic distance between the MAR at 26° S and the hotspots (31°-47° S) is inconsistent with present models of hotspot-ridge interaction[10,18,19] Moreover, this component is also recognized in MORBs from the North Atlantic[14,15] and elsewhere in the Indian Ocean[20,21] posing further difficulty for a simple hotspot contamination model Our preferred hypothesis[13,22] is that the component is pervasive in areas underlain by low-velocity, presumably hot, regions in the mantle[23] recognized by tomographic studies[24] These regions also are correlated with hotspot concentration and geoid anomalies[25,26] One such region is below the southern tip of Africa but extends north to the Azores[13,23]

New isotope data also add further evidence that the suggested inverse relationship between spreading rate and isotope variability[27,28] is not always valid Our results as well of those of others[16,17,29] show that apparently there is no such relationship Rather, both the fast-spreading EPR and the slow-spreading MAR are isotopically variable, the observed isotope difference is most probably due to regional differences of heterogeneous mantle components beneath spreading centres ☐

§ Instituto de Geologia, Universidad Nacional Autonoma de Mexico, Guanajuato, Mexico

CHARACTERIZATION of the lower continental crust is essential to understanding processes of crustal formation and evolution Many workers have concluded that the lower crust is composed of granulite-facies rocks (see, for example, refs 1, 2), but many exposed granulite-facies terranes seem to have mid-crustal rather than lower-crustal origins[3-5] Here we present new data from direct samples of the lower continental crust, in the form of metapelitic rock fragments brought to the surface by Quaternary volcanism in central Mexico These xenoliths contain exsolved ternary feldspars that record extremely high minimum metamorphic temperatures of 950-1,100 °C, the highest yet known to be preserved in deep-seated metamorphic rocks The metamorphism seems to be the result of underplating by basaltic magma and to be regional in extent Our barometry on these samples demonstrates that granulite-facies metamorphic rocks are present in the lower crust, and provides important constraints on tectonic models and interpretations of geophysical data. Chemical and textural evidence suggest that the xenoliths were not able to cool to below 850-900 °C before being entrained in their host magmas, indicating that the granulite-facies metamorphism occurred no more than ~30 Myr ago

So far most studies of xenoliths have focused on characterization of samples from the Earth's upper mantle[6], and only limited mineralogical and geochemical data have been obtained on xenoliths believed to be from the lower crust In addition, most studies of deep crustal xenoliths have concentrated on mafic and intermediate orthogneisses[6] Although modally less abundant than mafic orthogneisses, xenoliths with sedimentary protoliths may be more useful in providing definitive pressure information, because their mineralogy is often more appropriate for applying existing geobarometers[7-10]

Xenoliths of garnet-sillimanite paragneiss, occurring in Quaternary basanitic tuffs[11] from the central Mexican plateau in the state of San Luis Potosí, contain the assemblage garnet-sillimanite-mesoperthite-quartz-rutile-graphite, ±plagioclase-ilmenite-zircon-monazite The paragneisses are the major lithology at El Toro and represent ~10% of the xenolith population at La Joya Honda and Los Palau, mafic and felsic orthogneisses are the dominant lithologies at these two localities Here we present the pressure (P)-temperature (T) conditions of last equilibration for the paragneisses, and discuss the crustal level from which these samples were derived and the information they reveal about the crust beneath central Mexico

The paragneiss xenoliths were selected for detailed study based on mineralogical and textural similarities and the presence of univariant mineral assemblages with respect to barometric reactions Five samples are from the El Toro (ET) cinder cone, three are from La Joya Honda (LJH) maar, and two are from Los Palau (LP) maar Field relations are given elsewhere[11-13] The xenoliths range from 4 to 10 cm in diameter and appear fresh In general, all samples have similar mineral chemistries None of the selected samples exhibit distinct layering or mineral zoning Evidence of partial fusion is given by the ubiquitous occurrence of devitrified melt rims around garnets (see, for example, refs 14, 15) Quench textures in the melt rims consist of intergrowths of euhedral orthopyroxene, hercynite-spinel$_{ss}$, and interstitial glass and/or calcic plagioclase Stahle[14] has suggested that the breakdown of almandine garnet to orthopyroxene+hercynite+glass occurs rapidly at ~1,100 °C and 0 1-0 3 GPa

The compositions of the feldspars may provide constraints on the thermal histories of the xenoliths Plagioclase lamellae occurring within an alkali feldspar host and large plagioclase crystals not hosted by an alkali feldspar have very similar anorthite contents, within a given sample The plagioclase lamellae are typically slightly more potassic, indicating that the larger plagioclase crystals formed during cooling from an initially homogeneous alkali feldspar[16] Exsolution lamellae in feldspars are typically 10-30 µm in width Exsolved feldspar compositions are given in Fig 1*a* and Tables 1 and 2 The calculated

Sample locality abbreviations are given in the text

Mineral abbreviations Al, almandine, Py, pyrope, Gr, grossular, An, anorthite, Or, orthoclase, Fs, feldspar, Lam, lamellae Spessartine and albite can be calculated by difference from 100 Int, average minimum reintegrated temperature, and Exs, average temperature of exsolution using the model of Lindsley and Nekvasil[17]

* Bimodal distribution of reintegrated analyses observed for this sample

tie lines for 900 °C from the ternary feldspar model of Lindsley and Nekvasil[17] are shown at $P = 1\ 0$ GPa, the pressure dependence of the feldspar equilibria is from ref 18 The mesoperthites contain lamellar plagioclase ($An_{20-40}Ab_{49-62}Or_{8-28}$) and alkali feldspar ($An_{3-7}Ab_{20-45}Or_{47-76}$) (Tables 1 and 2) Graphical use of the ternary two-feldspar thermometer in ref 17 yields temperatures of ~800–950 °C for lamellae and host feldspars (Fig 1*a* and Table 2) These temperatures are much higher than any recorded by exsolved feldspars of exposed granulites[16,19] Reintegration of the mesoperthites by image analysis and broad-beam energy-dispersive analysis yields former ternary feldspar compositions of $An_{6-24}Ab_{35-57}Or_{22-55}$ (Tables 1 and 2) The compositions are among the most ternary reported from rocks of undoubted metamorphic origin[16,20-23] The isotherms of the ref 17 model require minimum temperatures of 950–1,125 °C (Table 2 and Fig 1*b*) for the reintegrated feldspars to be stable

Tie lines connecting exsolved alkali feldspar and plagioclase compositions for El Toro samples agree well with calculated tie lines[17] (Fig 1*a*) La Joya Honda and Los Palau samples give mixed results for exsolved compositions, as tie lines cross, indicating that these compositions may not represent equilibrium assemblages Nevertheless, the reintegrated values give similar minimum temperatures of 950–1,125 °C for the three localities Regardless of the details of exsolution processes, these mesoperthites yield minimum reintegrated temperatures that are considerably higher than those typically obtained for exposed granulites[16,19]

Figure 2 is a back-scattered electron image of a mesoperthite from sample ET24, quartz and rutile are also present The regular and continuous exsolution texture is typical of the mesoperthites, and is interpreted as evidence for slow cooling after regional metamorphism If the mesoperthites were produced during or after transport to the surface it is highly unlikely that the intergrowths would be so coarse and regular The homogeneity of lamellae and host compositions within each xenolith suggests that equilibrium between the feldspars was commonly attained, and no chemical gradients across lamellae have been identified with the electron microprobe The occurrence of mesoperthite inclusions in unzoned garnets from three samples (LP7, LP8, LJH32) seems to exclude an origin by epitaxial growth, as proposed[23] for mesoperthites from Kilbourne Hole (New Mexico), and indicates that the garnets

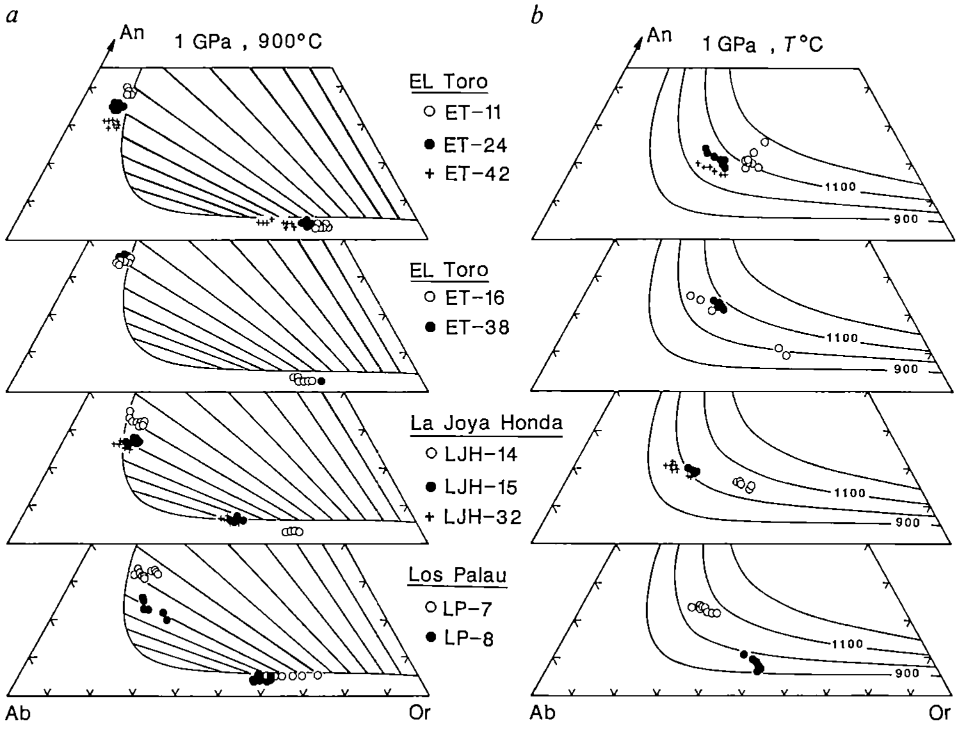

FIG 1 *a*, Exsolved feldspar compositions, for each xenolith, plotted on stacked anorthite (An)–albite (Ab)–orthoclase (Or) diagrams Symbols correspond to sample numbers as shown Isotherm and tie lines for 900 °C are shown at 1 0 GPa (ref 17) *b*, Reintegrated feldspar compositions plotted as in *a* Isotherms are shown at 1 0 GPa for 900, 1,000, 1,100 and 1,200 °C (ref 17) equilibrated with homogeneous ternary feldspars. Diffusion through the garnet would be required to permit re-equilibration of exsolved plagioclase compositions with matrix sillimanite.

The paragneiss garnets are homogeneous, with almandine ranging from 49 to 55 mol %, pyrope from 39 to 47 mol % and grossular from 3 to 5 mol % (Table 2). Garnets contain abundant inclusions of quartz, sillimanite and rutile. If the garnet in each sample equilibrated with the reintegrated ternary feldspar, sillimanite ($X_{Al_2SiO_5} = 0.99$), rutile ($X_{TiO_2} = 0.97$-0.98), ilmenite ($X_{FeTiO_3} = 0.81$-0.98) and quartz, barometry may be applied using the feldspar activity/composition relations of ref. 17. For garnet we have used the mixing model of Anovitz and Essene[24]. An ideal-solution model was used for rutile, sillimanite and ilmenite, and the activity of quartz was assumed to be unity. The garnet-sillimanite-quartz-plagioclase barometer[8] yields pressures of 0.9-1.4 GPa at $T = 950$-$1{,}200$ °C; the garnet-rutile-ilmenite-plagioclase-quartz barometer[9] also gives pressures of ~0.9-1.3 GPa. If lower pressure limits from the five samples that lack ilmenite are excluded, pressures of 0.9-1.3 GPa are obtained with the garnet-rutile-sillimanite-ilmenite-quartz barometer[10]. Pressures deduced from the three barometers correspond to depths of ~33-48 km (depending on temperature and the average specific gravity of the crustal rock column, chosen here to be 2.7). These depths are consistent with the estimated crustal thickness (35-45 km) in the study area[25-27], and show that the xenoliths sample the region of the crust/mantle boundary in central Mexico.

The mesoperthites provide evidence for regional metamorphism at $T > 950$-$1{,}125$ °C, higher than any temperatures recorded previously in regionally metamorphosed rocks of undoubted sedimentary parentage. The metamorphism spanned an area of at least 100 km^2 in central Mexico and may be related to the occurrence of similar metapelitic xenoliths 1,600 km to the north at Kilbourne Hole in New Mexico in the United States. We conclude that the lowermost crust of central Mexico was heated to ~1,100 °C by underplated basaltic magmas[5,28]. The base of the crust was subsequently cooled to ~900 °C, as recorded by the exsolved feldspars. We believe the xenoliths never equilibrated below 900 °C and were excavated from nearly the depth they record by ascending basanitic magmas. Such extreme quench temperatures (800-950 °C) for the feldspars suggest recent granulite facies metamorphism of the base of the crust in central Mexico; a mid-Tertiary underplating event would be consistent with moderate cooling rates of 5-10 °C Myr^{-1} for a regional terrane. These inferences are consistent with data in a chronological study of Kilbourne Hole metapelites, in which a metamorphic age of 1.6 Gyr was obtained from Rb-Sr isochrons of adjacent layers and an age of 34 (±14) Myr from mineral isochrons[29].

We have attempted to unravel the cooling history of the xenoliths using data on the coarsening of exsolution lamellae in alkali feldspars[30], and the homogenization of plagioclases[31]. Data from coarsening experiments[30] indicate that lamellae of width 10-30 μm could be produced in 10^5 yr at 800 °C, and 10^{-3} yr at 1,100 °C (with an initial lamella width of 0 μm), but calculated homogenization rates[31] are orders of magnitude slower. At 1,100 °C, lamellae 10 μm wide would be homogenized in $10^{4\pm1.5}$ yr, and $\sim10^{10\pm1}$ yr are needed for 10-μm-wide lamellae at 800 °C. Although the homogenization rates, for which experiments involved coupled NaSi-CaAl diffusion[31], are consistent with the preservation of feldspar lamellae in the xenoliths, the coarsening estimates are in sharp disagreement with our hypothesis of slow cooling subsequent to a mid-Tertiary regional metamorphic event. Perhaps the strongest evidence against a mesoperthite origin related to the host basalt is the absence of coarse perthites in volcanic rocks; to our knowledge all volcanic perthite occurrences are cryptoperthites/microperthites with lamellae that are ≤1 μm wide. We believe that available experiments on lamellar coarsening are not relevant to ternary mesoperthites because the experiments were done on cryptoperthites with coherent structures at a pressure of 10^5 Pa (1 atm) and at temperatures <600 °C, and, most importantly, they were done on binary alkali feldspars. Although higher temperatures should enhance coarsening, coupled Al/Si diffusion, required for exsolution of ternary feldspars, will greatly hinder coarsening[30-32]. As the Mexican mesoperthites exsolved on the strain-free solvus with non-coherent structures, a mechanism involving nucleation and growth is required—a slower process than spinodal decomposition. Coarsening rates calculated from existing experimental data are inconsistent with

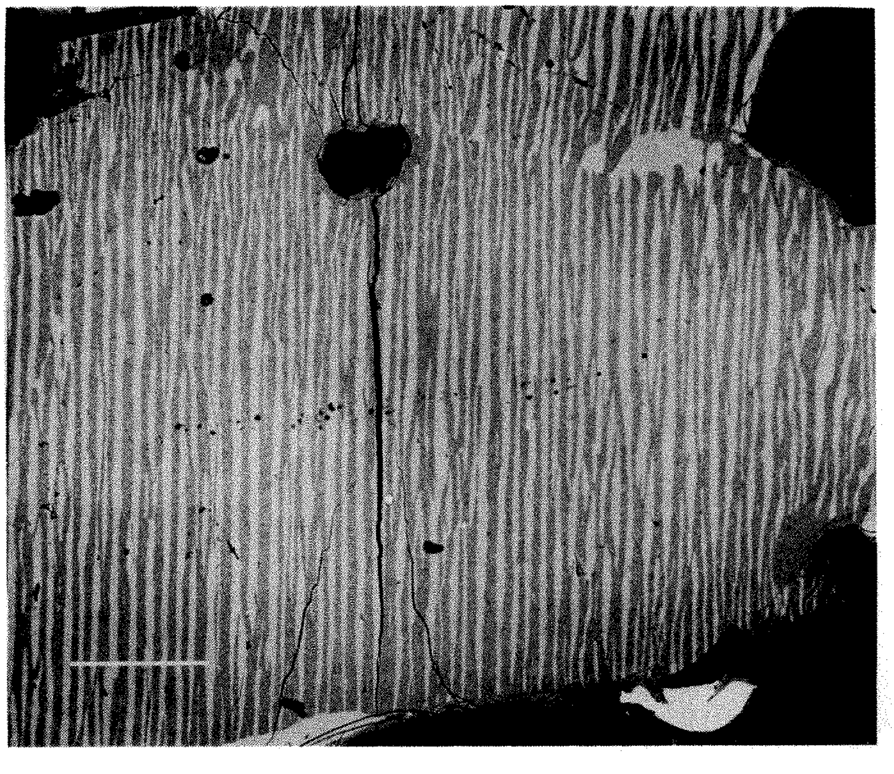

FIG. 2 Back-scattered electron image of a typical mesoperthite (sample ET24) showing the regular and continuous nature of exsolved plagioclase lamellae (darker bands). Quartz (dark) and rutile (light) are also present. Scale bar = 150 μm.

Sampling for each species was generally restricted to small (<6 ha) areas. When this was not true, data were combined from several small areas when an F_{ST} close to zero indicated homgeneity, or treated separately when there was significant differentiation (*P. exclamans*).

of some species will overwinter and serve as helpers to one of their natal nestmates who was not the queen of the natal nest[13,14,20], so their relatedness to the brood they help rear is only half of their relatedness to the nestmate who becomes the queen.

When relatedness to colony mates is less than $\frac{1}{2}$, there are two possible explanations for the selective maintenance of eusociality. The first is that individuals may be able to direct their aid towards colony mates who are especially closely related, perhaps rearing full sisters even when most colony mates are half-sisters. Such discrimination has been demonstrated in honeybees[21,22], though the effect is generally weak. It requires that individuals use cues learned from their own phenotypes. This seems unlikely for *Polistes* because adults isolated from their nest subsequently fail to distinguish kin from non-kin[23]. These experiments suggest that kin-recognition cues are derived from the nest or brood, sources that are unlikely to carry information useful for within-colony discriminations. Thus, the available evidence seems to support the second possible explanation, which is that reproductive altruism may evolve even when $r < \frac{1}{2}$. According to inclusive fitness theory[1,2], helping is favoured when $rb > \frac{1}{2}c$, where b is the fitness benefit to the individual helped, c is the cost to the helper, r is relatedness to the brood reared, and $\frac{1}{2}$ is the relatedness of the helper to its own offspring. So even when $r < \frac{1}{2}$, altruism can be favoured when the benefit is sufficiently higher than the cost. Several studies have shown that benefits may exceed costs in *Polistes*[24-27].

Although the data do not support the prediction that individuals usually gain a relatedness advantage by rearing offspring that are not their own, they do confirm some of Hamilton's ideas[1,2]. With the addition of our 14 species to the 3 previously studied primitively eusocial species[9-12], there are sufficient data to support the generalization that relatedness is always fairly high in species without morphological castes. This permits us to draw an interesting contrast to species with castes. In five species of social wasps with at least some degree of caste development, relatedness takes on lower values, ranging from 0.11 to 0.40 (refs 19, 28). For ants with highly specilized worker castes, relatedness within colonies is variable, but is extremely low in some species[29-31]. Thus when individuals are constrained by a specialized worker morphology they may accept a subordinate, nonreproductive role to aid individuals that may not be highly related. However, as expected from inclusive fitness theory, to the extent that individuals are unconstrained in their choices, they perform such sacrifices only for rather close relatives. □

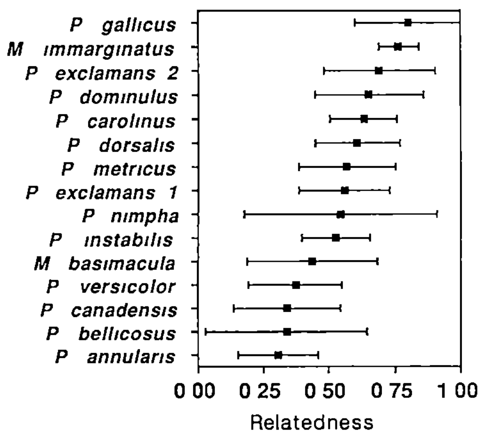

FIG. 1 Point estimates and 95% confidence intervals for relatedness among female nestmates in *Polistes* and *Mischocyttarus*. Confidence intervals are calculated using values of the t-distribution with degrees of freedom equal to one less than the number of colonies.

Telemetered *in vivo* strain analysis of locomotor mechanics of brachiating gibbons

Sharon M. Swartz*†‡, **John E. A. Bertram**§ & **Andrew A. Biewener***§

* Committee on Evolutionary Biology and §Department of Organismal Biology and Anatomy, The University of Chicago, 1025 East 57th Street, Chicago, Illinois 60637, USA
† Yerkes Regional Primate Research Center, Emory University, Atlanta, Georgia 30322, USA

THE slender elongated form that is characteristic of the forelimb long bones of gibbons (*Hylobates*) has long been attributed to their functional adaptation to habitual armswinging locomotion[1–3], although potential selective advantages of this morphology for brachiation have yet to be demonstrated If the forces exerted on the limb skeleton during brachiation indeed differ greatly from those of other locomotor modes, then the changes in skeletal loading accompanying a shift in locomotor behaviour could favour alterations in skeletal morphology in brachiating lineages *In vivo* skeletal strain patterns recorded by using radiotelemetry during brachiation indicate that the forelimb bones of the gibbon are loaded in substantial tension and show reduced bending and compression in comparison with those of other mammals We suggest that this unique loading regime could have contributed to the evolution of the distinctive morphology of hylobatid limbs

Theoretical analyses of the mechanics of brachiation have modelled gibbon locomotion after ideal pendula[4,5], these models predict that the supporting limb is subjected to axial tension under the load exerted by gravity acting on the animal's mass Correspondingly, it has been suggested that tensile loading is the key feature distinguishing brachiation from walking, running and jumping[6,7] However, models of the response of bone to mechanical loading have argued against the possibility that bones are ever regularly subjected to net tension[8] Furthermore, because all vertebrate long bones so far studied experience primarily bending and compressive forces[9–12], axial tensile loading is a novel loading regime for a limb This would alter the criteria for natural selection acting on skeletal design, given that a structure's ability to resist tensile, but not compressive and bending forces, is independent of both length and cross-sectional shape, and that bending, particularly due to eccentric loads, increases in proportion to length[13] If, in brachiation, bone compression and bending are minimal and tension predominates, an increased bone length will not be structurally disadvantageous

Tensile loading may not characterize suspensory support, however, because skeletal loading depends not only on external forces but also on internally transmitted, largely compressive muscle forces To resolve this issue, we recorded *in vivo* surface bone strains at the dorsal and ventral midshaft of the humerus, radius and ulna of four freely brachiating white-handed gibbons (*Hylobates lar*) by using radiotelemetry[14] Principal strain magnitudes and their orientations with respect to the bone's long axis were determined for each rosette strain gauge, and used to characterize bone loading[15]

For all forelimb long bones, principal strain magnitude peaked at midsupport phase of the swing, as the animal's body reached the bottom of the arc swept out by the forelimb, near-zero strains were obtained when the limb was not grasping a support (Fig 1) Considerable variability in strain pattern and peak magnitude among swings was observed, contrasting with the stereotypic patterns recorded in walking and running animals[9,11,16] This seems to be due both to the unrestricted movement in a large enclosure compared with controlled treadmill locomotion, and to development of localized strain from muscles attaching near the gauges

The largest principal strains recorded on the dorsal and ventral surfaces of the ulna were tensile, similar in magnitude, and oriented close to the bone's longitudinal axis, indicating overall axial tension (95% of total strain) with a small amount of bending (Fig 2*a*, Table 1) In the radius, principal strains were again oriented longitudinally, and showed substantial compression on the ventral midshaft surface with smaller tensile strains dorsally (Fig 2*b*, Table 1) Unlike the ulna, loading of the radius was characterized by dorso-ventral bending (83% of total strain) superimposed on axial compression In the humerus, peak principal strains for both the dorsal and ventral surfaces were tensile but differed in magnitude, and strain orientation deviated 45-60° from the bone's axis (Fig 2*c*, Table 1) The humerus thus experienced a combination of axial tension, torsion (indicated by the off-axis orientation) and bending

The overall axial tension recorded from the ulna was similar (within 11%) to values expected for a bone functioning as a passive suspending cord of a pendulum[14] Given this tensile loading and the predicted net tensile loading of the forelimb as a whole, the bending and compression of the radius may seem surprising This loading disparity arises from differences between the two bones in morphology, transmitted muscular force, and weight-support roles In long bones, the main source of bending may be axial force exerted about the longitudinal curvature of the bone[17], in the gibbon, radii are seven times more curved than ulnae[14] Muscle force is typically the greatest constituent of axial force exerted on long bones (generally two to three times the magnitude of the reaction force of the body acting against the ground[9]) Gibbon forearm flexor muscles are positioned ventrally so that their pull will bend the bone in a ventrally concave fashion, dictated by the radius's dorso-ventral curvature, and during the support phase of brachiation, flexor activity is marked[18–20] Additionally, weight is transferred in tension directly from the humerus to the ulna through the interlocking humero-ulnar joint, whereas the direct connections from humerus to radius are exclusively ligamentous, and the interosseus membrane joining the two forearm bones is not stiff

TABLE 1 Mean peak maximum principal strain magnitudes and orientations

	$\mu\varepsilon$	(s d)	Orientation	(s d)
Ventral ulna	+1,421	(337)	2°	5°
Dorsal ulna	+1,270	(167)	6°	1°
Ventral radius	−1,638	(453)	1°	2°
Dorsal radius	+746	(248)	5°	4°
Ventral humerus	+419	(180)	−44°	3°
Dorsal humerus	+1,492	(71)	+62°	4°

Mean peak-maximum principal strain magnitudes (in microstrain, $\mu\varepsilon$) and orientations (in degrees deviation from the longitudinal axis of the bone) for each recording site Tensile strains are positive values, compressive strains negative Orientations are positive if they deviate from the bone's long axis in the proximo-medial direction, negative if they deviate in the proximo-lateral direction The s d of the values for each site are given in parentheses after the mean value or thick enough to transfer substantial stress between them Compression of the radius indicates both that muscle force is preferentially exerted through the radius rather than through the ulna, and that this force provides the primary loading of the radius, whereas the animal's body weight is transferred from the humerus to the hand through the ulna

---

‡ Present address Departments of Cell Biology and Anatomy and Anthropology Northwestern University 303 East Chicago Avenue Chicago Illinois 60611 USA

The lesser tensile strain recorded from the humerus compared with that recorded from the ulna probably results from compressive forces exerted by the arm and shoulder musculature[18-20] counteracting tension from suspensory weight support, and the six-times greater cross-sectional area of the humerus[14] The curvature of the humerus and the differential muscle activity on the flexor and extensor aspects of the arm probably produces the bending we observed The significant torsion of the humerus reflects the bone's resistance to the lateral rotation of the gibbon's body about the long axis of the limb during the swing[21] During this movement, the humerus rotates little at the shoulder joint and the supporting hand remains stationary[22] Thus, free rotation of the radius and proximal carpus about the humerus and distal carpus provides propulsive motion[22,23] while freeing the forearm bones from torsion Stabilization at the shoulder combined with the hinge-like morphology of the humero-ulnar joint can then result in torsional loading of the humerus

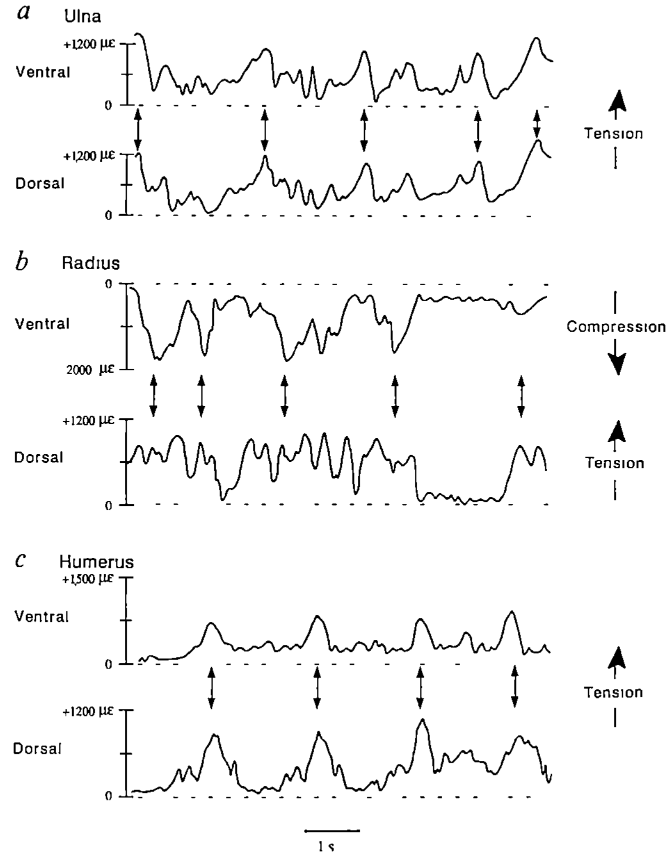

FIG 1 Representative principal strain recordings from the ventral and dorsal midshaft surfaces of the ulna (*a*), radius (*b*) and humerus (*c*) of one gibbon for a duration of 8 s, correlated with swing kinematics based on light films (60 frames per second) taken during recordings The midsupport phase of each swing is indicated by an upward pointing arrow Strain magnitudes are in microstrain (strain $\times 10^{-6}$) Tensile strains are positive and compressive strains are negative Bone strains reached their greatest absolute values at midswing, and strain values return close to zero as the limb is swung forward (protracted) during the nonsupporting phase of the locomotor cycle (analogous to the swing phase of terrestrial locomotion) All recordings were made at the Yerkes Regional Primate Research Center, Emory University, Atlanta, Georgia By using aseptic surgery under general anaesthesia, we attached rosette strain gauges with a self-catalysing cyanoacrylate adhesive to the dorsal and ventral midshaft cortices of the right humerus and left radius and ulna at the bones' diaphyses, as near as possible to midshaft level but in areas free of direct muscle attachment to minimize localized distortions in overall bone strain due to muscle pull The procedure was similar to that previously described[9,24] Lead wires were led subcutaneously up the arm and over the shoulder, externalized through the skin between the scapulae at approximately the level of the third thoracic vertebra, and soldered to a connector, all lead wires were left slack to permit rapid and forceful limb movements without dislodging the gauges Following 2–3 days post-operative recovery, *in vivo* strain data were then recorded over a 2–3 day period using radiotelemetry Each gibbon carried a strain transmitter on its back as it brachiated freely in a large (9 × 2 × 3 m) outdoor enclosure The eight bridge channels were multiplexed to a single channel telemetry transmitter (Transkinetics TXM-205, frequency response, 35 kHz, transmission range, 50 m) which was housed in the pocket of a vest-style harness that fitted snugly around each animal's chest and back Each channel was sampled at a frequency of 125 Hz After 2–3 days of recordings, all gauges and wires were removed from the animals

Our results show that some bones can be regularly loaded in net tension Hence, models of adaptive bone remodelling positing bone resorption under tensile loading must be revised Our results also indicate a new explanation for the elongation of the forelimb skeleton in gibbons that is based on the reduction of compressive and bending loads inherent in suspensory support In general, limb elongation is advantageous in terms of increased stride length, velocity and greater reach, especially in grasping primates However, greater limb-bone length is probably constrained in most terrestrial mammals partly by the risks engendered by excessive bending and the associated large strains when long slender bones experience off-axis loading In contrast to terrestrial locomotion, in which external loading (weight support) and muscle forces are additive in generating compressive

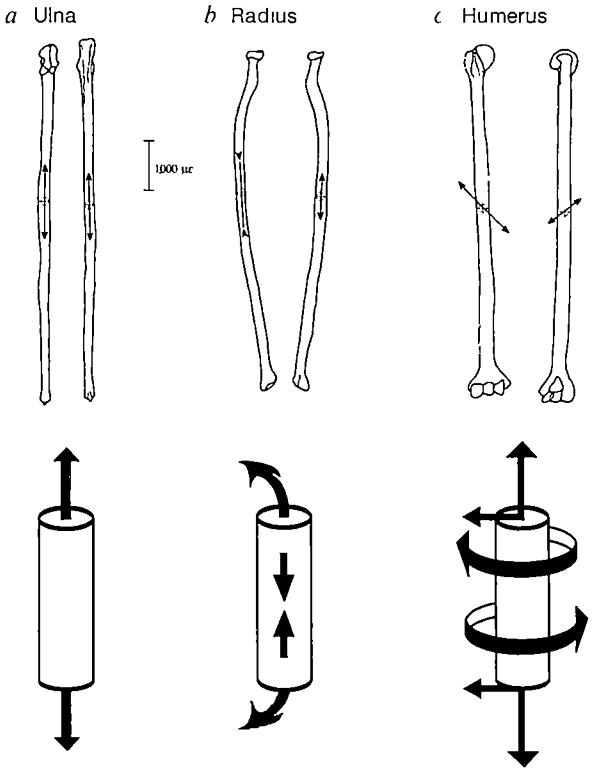

FIG 2 Diagramatic views of the ventral (left) and dorsal (right) ulna (*A*), radius (*B*) and humerus (*C*) with strain-gauge attachment sites indicated by the cross-hatched circles Vectors depicting mean peak principal-strain magnitude and orientation with respect to the bone's longitudinal axis as recorded from the implanted strain gauges are indicated at each gauge attachment site, outwardly directed arrows indicate tension, whereas inwardly directed arrows indicate compression The cylindrical model below each bone schematically shows each bone's overall loading mode ulna, axial tension, radius, compression and dorsoventral bending, and humerus, tension, dorsoventral bending and torsion

and bending stresses, muscle forces (compressive) and external weight support (tensile) will oppose one another during brachiation, reducing net axial strain in the skeleton. Brachiation further reduces bending of the forelimb skeleton by suspending the animal's weight directly in line with the bones' long axes at the time in the swing cycle when external forces are greatest[14]. By reducing bending, selection for increased bone length in brachiators could be favoured with minimal risk or increased strain and hence bone failure. ☐

EVIDENCE exists that the specification of afferent nerves and their central connections in the embryo may depend in part on influences from the peripheral target innervated[1–7]. We have now investigated whether such peripheral determination persists in the adult rat using the unmyelinated afferent system of C fibres, which differ chemically in the adult depending on their target[8–11]. We have previously shown that if the cutaneous sural nerve and the muscle gastrocnemius nerve are cross-anastomosed so that they grow to each other's target, the A fibres establish functional endings and the C fibres change their chemistry to that which is appropriate for the new target[9,12–14]. Here we report that in normal adult rats, a short train of stimuli to the cutaneous sural nerve produced a brief facilitation of the flexion reflex, lasting on average only 5 min, whereas similar stimulation of the gastrocnemius-muscle nerve enhanced this reflex for an average of 54 min. In cross-anastomosed animals, stimulation of the gastrocnemius nerve (innervating skin) induced a brief potentiation of the flexion reflex, lasting on average only 3 min. By contrast, stimulation of sural nerve (innervating muscle) produced a potentiation of this reflex lasting 57 min. Thus the ability of adult afferent nerves to potentiate the flexion reflex depends on the target with which they make contact. We propose that tissue-specific factors influence some of the central actions of primary afferent neurons in the adult.

In adult decerebrate low-spinal rats, with normal nerves or cross-anastomosed or self-anastomosed sural nerves (s n) and gastrocnemius nerves (made 10–14 weeks previously), the flexion reflex was measured as the discharge in small branches of the nerve to biceps femoris/semitendinosus containing a few motorneurons[15]. The flexion reflex was elicited by applying a standard 3-s suprathreshold pinch stimulus to the middle three toes of the ipsilateral hindpaw, and the multiunit discharge was recorded and counted for the 3 s of the stimulus. The reflex was initially similar in all animals and consisted of a phasic high-frequency discharge lasting 0.5-2 s, and its magnitude was stable from trial to trial. Repeated determinations of the flexion reflex were made at 5-min intervals. After obtaining consistent control responses over at least a 20 min period, conditioning stimuli of 20 shocks at C-fibre strength (5 mA, 500 μs, 1 Hz) were given to the normal or anastomosed nerves, and the subsequent changes in the size of the flexion reflex were determined at 1-min intervals for 5 min, and at 5-min intervals thereafter.

Conditioning the normal sural nerve increased the response to the standard pinch stimulus both in terms of the frequency of firing of motorneurons and duration for which they fired. The facilitation persisted for on average 5±1.6 min (±s e m). The magnitude of the enhancement of the flexion reflex was typically 200–300%. Figure 1 shows the time course of change in one typical case.

When the same conditioning stimulus was applied to normal g n there was an enhancement of the flexion reflex lasting for an average of 54±8.3 min. A typical example is shown in Fig 1. The difference in duration of facilitations was highly significant ($P < 0.01$), and is similar to that previously reported for normal animals[15,16]. The modulation induced by stimuli conditioning g n often appeared to have two phases: an early phase resem-

TABLE 1 Enhancement of flexion reflex induced by conditioning stimulus

Nerve stimulated	Average enhancement (min)	s e m	No
Normal s n	5	1.6	28
S n reinnervating skin	2	0.4	4
S n innervating muscle	59	9.4	5
Normal g n	54	8.3	16
G n reinnervating muscle	77	11.3	3
G n innervating skin	3	0.7	6

The duration of enhancement of flexion reflex (in min) induced by a conditioning stimulus (20 shocks, 5 mA, 500 μs, 1 Hz) delivered either to the normal s n or g n, or to s n and g n which had been cut and had reinnervated their own normal targets, or to s n and g n which had innervated inappropriate targets after cross-anastomosis.

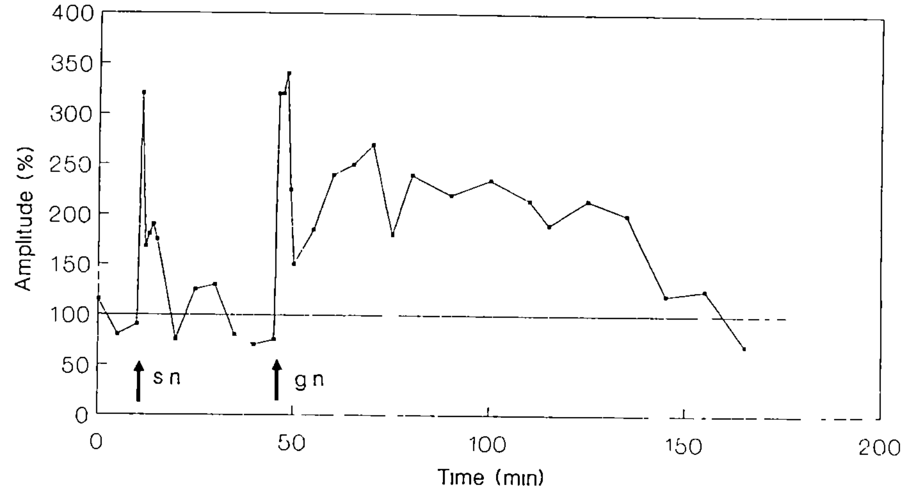

FIG 1 The time course of enhancement of the flexion reflex in one normal animal after a conditioning stimulus train to the s n (at a time indicated by arrow marked s n) and the g n (at a time indicated by arrow marked g n) The magnitude of the flexion reflex (the number of discharges evoked by the standard pinch stimulus) is plotted as a percentage of the average level determined in the control period Note that whereas the s n produced only a short-lived facilitation, the g n produced a more prolonged facilitation

METHODS A small branch of the nerve to biceps femoris was dissected, typically containing 5-10 motorneurons activated by the pinch test stimuli Multiunit efferent action potentials were recorded using conventional techniques with amplifier filters set at 1 kHz to 8 kHz, and counted with a window discriminator set to detect all voltage fluctuations greater than three times the noise level The total number of counts occurring in the 3 s after the pinch stimuli are plotted here as a percentage of the counts obtained in the control period The duration of facilitation was measured as the time taken for the amplitude of the reflex to fall below 120% of the control level

bling that seen with the conditioning of s n and a later phase which reached a maximum with a latency of 10-20 min The order of presentation of conditioning stimuli did not affect the nature of facilitations

Recordings on cross- or self-anastomosed nerves showed that the nerves had successfully innervated skin or muscle[12 13] The distal nerve trunk appeared to be of a normal size We have previously shown that >70% of peripheral fibres successfully negotiate the anastomosis and regenerate to the inappropriate target[12 13]

The conditioning stimuli produced very different changes in animals with the cross-anastomosed nerves Stimuli to the g n , then innervating skin, resulted in an enhancement of the flexion reflex, but this lasted only 3±0 7 min (compared with 54± 8 3 min in normal animals, $P<0\ 01$, Fig 2) Stimulation of s n , then innervating muscle, produced a long-lasting facilitation, starting within 1 or 2 min after application of the conditioning stimulus, and lasting 59±9 4 min (compared with 5 min in normal animals, $P<0\ 01$) These facilitations also tended to show an early and a late phase, like the effect seen in normal g n Table 1 shows the duration of the effects elicited by trains of conditioning stimuli to the different nerves

For self-anastomosed nerves, the nature of the flexion reflex and the facilitatory effects of conditioning the s n and g n were quantitatively similar to those in intact animals That is, conditioning the s n enhanced the flexion reflex for 2±0 4 min, and conditioning the g n enhanced the reflex for 77±11 3 min ($P>0\ 05$, compared with intact controls in both cases, Table 1) One typical example is shown in Fig 3 The onset of facilitation was also similar, in all cases beginning 1-3 min after the conditioning stimulus The only apparent difference between responses in intact and self-anastomosed nerves was in the magnitude of facilitation, which tended to be less in the latter group, typically 150-250% Hence, the changes seen with cross-anastomosed nerves cannot be attributed to a nonspecific consequence of nerve section or regrowth

To avoid the possibility of spread of electric current, conditioning by the injury discharge resulting from nerve section was used Wall and Woolf[16] noted that enhancement of the flexion reflex could be triggered by the injury discharge produced by section of peripheral nerves as well as by electrical stimulation In normal animals, the section of s n induced a relatively short-lived enhancement of the flexion reflex, whereas that from the section of g n was much more prolonged ($P<0\ 01$, see Table 2) Similar facilitations were seen with self-anastomosed nerves (Table 2) By contrast, in the animals with

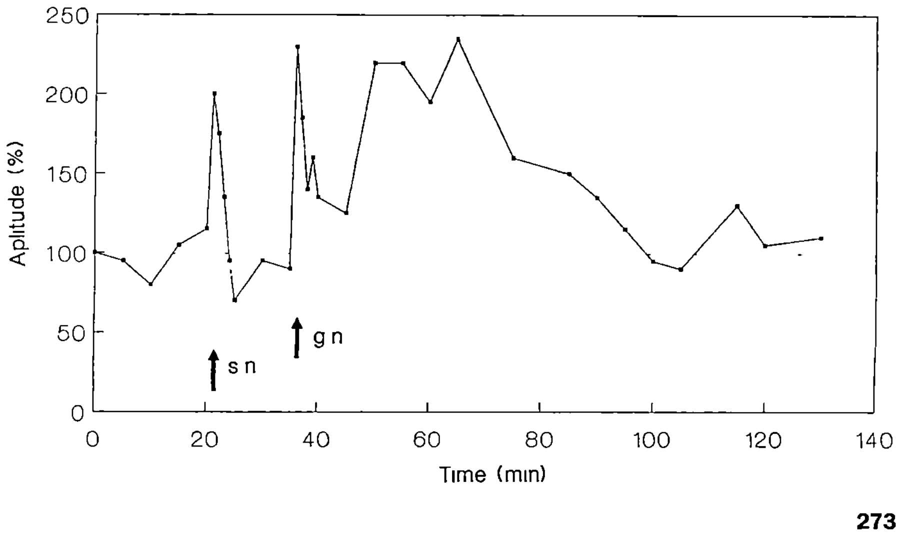

FIG 2 The time course of enhancement of the flexion reflex in one animal with cross-anastomoses of the s n and g n The figure is constructed in the same way as Fig 1 Note that in this animal, in contrast to normal animals, the s n (innervating muscle) produced a long-lasting facilitation, whereas the g n does not

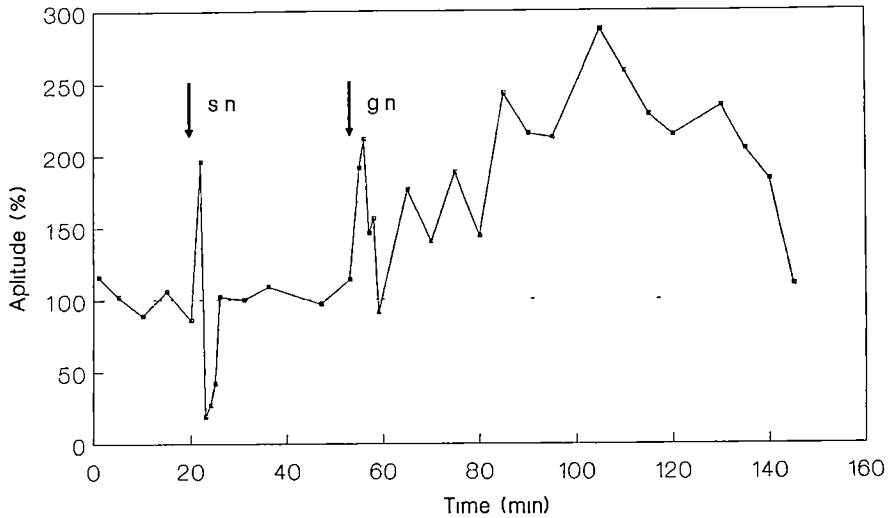

FIG 3 The time course of enhancement of the flexion reflex in one animal with self-anastomoses of the s n and g n The figure is constructed in the same way as Fig 1 Note that in this animal, like animals with intact nerves, the g n (innervating muscle) produced a long-lasting facilitation, whereas the s n (innervating skin), does not

cross-anastomoses, the section of s n (supplying muscle) elicited long-lasting effects, whereas the section of the g n (innervating skin), only short-lasting changes ($P<0$ 01, Table 2)

The facilitation of the flexion reflex is known to depend on the activation of afferent C-fibers and to be due to an altered heterosynaptic excitability within the spinal cord[16 17] When the sural or gastrocnemius nerves reinnervate inappropriate tissue they change their normal characteristics and take on those appropriate for the tissue that they then innervate That is, s n afferents innervating muscle induce long-lasting facilitation, whereas the g n afferents innervating skin lose this capacity These changes in the spinal cord are presumably secondary to alterations in the properties of primary afferents when they innervate inappropriate tissue The inappropriate tissue is presumably the skin or muscle itself, although it could be the non-neural elements in the nerves leading to the tissue We have previously shown that such inappropriate reinnervation can alter the histochemistry of primary afferents Normal s n C-fibres contain high levels of substance P and the enzyme FRAP (fluoride resistant acid phospatase), whereas normal g n afferents do not, when these nerves are cross-anastomosed, the expression of these markers become appropriate for the tissue innervated[9 14] It could be that the altered ability to modulate the flexion reflex reflects some parallel change in the histochemistry of the primary afferents

Thus, peripheral targets can not only regulate some properties of primary afferents, but can extend this influence to a control of their central effects In adult animals, isolation of afferents from their peripheral targets by axotomy can produce several plastic changes within the central nervous system, including a reorganization of the receptive fields of dorsal horn cells[18-21] The strength of monosynaptic connections from Ia fibres may be reduced when these fibres inappropriately reinnervate non-spindle targets[22] We have recently found[24] that when gastrocnemius afferents regenerate to skin, there is a dramatic change in the central responses after their stimulation In normal animals, stimulation of unmyelinated g n afferents excites relatively few dorsal-horn cells In animals with cross-anastomosed nerves, the central effect of gastrocnemius afferent barrages is greatly enhanced and many more dorsal-horn neurons are excited by these afferents This too is not a non-specific effect due to axotomy or regrowth, but is dependent on some influence arising from the new tissue innervated The changes we have reported here could similarly indicate the presence of tissue-specific trophic influences, the effects of which on primary afferents could further influence the establishment or maintenance of specific patterns of central responses ☐

TABLE 2 Enhancement of flexion reflex induced by injury discharge

Nerve stimulated	Average enhancement (min)	s e m	No
Normal s n	13	2 7	7
S n reinnervating skin	7	2 8	4
S n innervating muscle	67	8 3	4
Normal g n	64	7 5	13
G n reinnervating muscle	52	4 7	3
G n innervating skin	4	1 1	4

The duration of enhancement of flexion reflex (in min) induced by the injury discharge from axotomy of either the normal s n or g n, or of self-anastomosed or of cross-anastomosed s n and g n innervating either appropriate or inappropriate targets

FMRFamide reverses protein phosphorylation produced by 5-HT and cAMP in *Aplysia* sensory neurons

J. David Sweatt*, Andrea Volterra, Brian Edmonds, Kevin A. Karl, Steven A. Siegelbaum & Eric R. Kandel

Howard Hughes Medical Institute and Center for Neurobiology and Behavior, College of Physicians and Surgeons of Columbia University, 722 West 168th Street, New York, New York 10032, USA

NEUROTRANSMITTERS can modulate neuronal activity through a variety of second messengers that act on ion channels and other substrate proteins[1-3]. The most commonly described effector mechanism for second messengers in neurons depends on protein phosphorylation mediated by one of three sets of kinases: the cyclic AMP-dependent protein kinases[4,5], the Ca^{2+}–calmodulin-dependent protein kinases[3,6], and the Ca^{2+}–phospholipid-dependent protein kinases[7]. In addition, some neurotransmitters and second messengers can also inhibit protein phosphorylation by lowering cAMP levels (either by inhibiting adenylyl cyclase[8] or activating phosphodiesterases[9]). This raises the question: can neurotransmitters also modulate neuronal activity by decreasing protein phosphorylation that is independent of cAMP? Various biochemical experiments show that a decrease in protein phosphorylation can arise through activation of a phosphatase[10,11] or inhibition of kinases[12,13]. In none of these cases, however, is the physiological role for the decrease in protein phosphorylation known. Here we report that in *Aplysia* sensory neurons, the presynaptic inhibitory transmitter FMRFamide decreases the resting levels of protein phosphorylation without altering the level of cAMP. Furthermore, FMRFamide overrides the cAMP-mediated enhancement of transmitter release produced by 5-hydroxytryptamine (5-HT), and concomitantly reverses the cAMP-dependent increase in protein phosphorylation produced by 5-HT. These findings indicate that a receptor-mediated decrease in protein phosphorylation may play an important part in the modulation of neurotransmitter release.

5-HT and FMRFamide produce opposing modulatory changes in the electrical excitability of the sensory neuron and in transmitter release from the sensory neuron presynaptic terminals[14-16]. By acting through cAMP-dependent phosphorylation, 5-HT produces prolonged all-or-none closure of the S-K^+ channels, which results in a slow depolarization and an increase in the duration of the action potential, contributing to presynaptic facilitation[14]. By contrast, the neuropeptide FMRFamide, acting through the lipoxygenase metabolites of arachidonic acid[17], produces an increase in the probability that an S-channel is open, which results in a slow hyperpolarization and a decrease in the action potential duration, which contributes to presynaptic inhibition[15].

Moreover, the actions of 5-HT and FMRFamide are not symmetrical. Simultaneous application of the two transmitters does not result in simple algebraic summation of excitatory and inhibitory actions, rather, the inhibitory action of FMRFamide antagonizes or overrides the excitatory action of 5-HT. This override occurs at the level of single S-channel activity, where FMRFamide re-opens S-channels closed by 5-HT or cAMP[15]. Here we show that this override is also evident in the action of FMRFamide and 5-HT on transmitter release (Fig. 1*a*). The synaptic potential produced in a motorneuron in response to firing the sensory neuron was decreased by FMRFamide (presynaptic inhibition) to 11% of the control synaptic potential

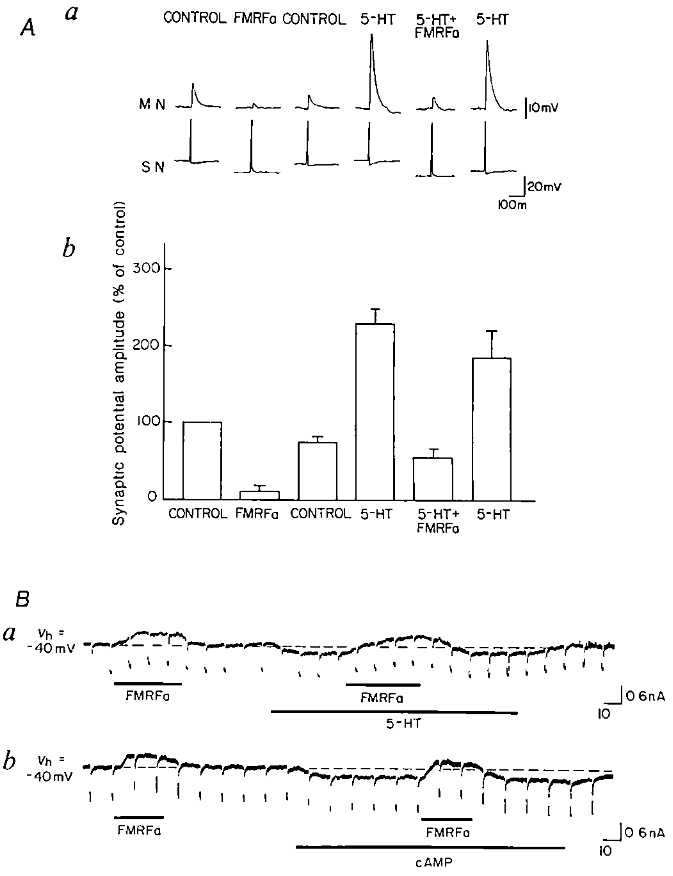

FIG. 1 FMRFamide (FMRFa) antagonizes the actions of 5-HT and cAMP. *A*, FMRFamide produces presynaptic inhibition and antagonizes presynaptic facilitation with 5-HT. *Aa*, Intracellular recordings of membrane potential from motor neurons (top) and sensory neurons (bottom) in response to brief depolarizing current stimuli to sensory neurons. Action potentials in sensory neurons elicit a fast excitatory postsynaptic potential (e.p.s.p.) in motor neurons. *Ab*, Average data from five experiments. Errors bars show s.e.m. Application of 10 µm FMRFamide alone inhibits the synaptic potential recorded in a follower neuron to 11% of that of the initial control. The same dose (10 µm) of 5-HT produces facilitation of the synaptic potential to 229% of that of the control. When FMRFamide is applied in the presence of 5-HT, the synaptic potential is reduced to a level slightly below that of the control (55%). *Ba*, Antagonism by FMRFamide of membrane current response to 5-HT. First application of FMRFamide (10 µm) produces a 450 pA increase in outward S-channel current (V_m = −40 mV). Application of 5-HT then produces a 270 pA decrease in outward S-channel current. Subsequent application of FMRFamide in the presence of 5-HT produces a 660 pA increase in outward current, so that net membrane current approaches peak outward level in FMRFamide alone. *Bb*, Antagonism of current response to cAMP by FMRFamide. V_h, Holding voltage. First application of FMRFamide produces a 420 pA increase in outward current. Next, application of 200 µM chlorophenyl-thio-cAMP causes a 300 pA decrease in outward current. Finally, application of FMRFamide in the presence of cAMP causes a 570 pA increase in outward current. On average, FMRFamide alone causes an increase in outward current of 0.28 nA ± 0.06 (±s.d., n=6, V_m = −40 mV), whereas cAMP alone causes a mean decrease in outward current of 0.2 ± 0.04 nA (±s.d., n=6, V_m = −40 mV). In the maintained presence of cAMP, FMRFamide induces a larger increase in outward current of 0.4 ± 0.007 nA (±s.d., n=6, V_m = −40 mV).

METHODS. *A*, Sensory neurons were grown in cell culture, with their follower motor neurons. Sensory neurons and motor neurons were impaled with a conventional intracellular microelectrode to record membrane potential under current clamp. Action potentials were elicited in the sensory neurons once every 40 s using a 5 ms depolarizing current pulse, and the fast e.p.s.p. were recorded in the motor neuron. *B*, Membrane current was measured from sensory neurons in intact abdominal ganglia by using a single microelectrode switched voltage-clamp (Axoclamp 2A, Axon Instruments). Electrode resistance was 10 MΩ and switching frequency was 6–8 kHz. Current records were filtered at 300 Hz. Hyperpolarizing command voltage-clamp steps of 10 mV were applied at 0.1 Hz.

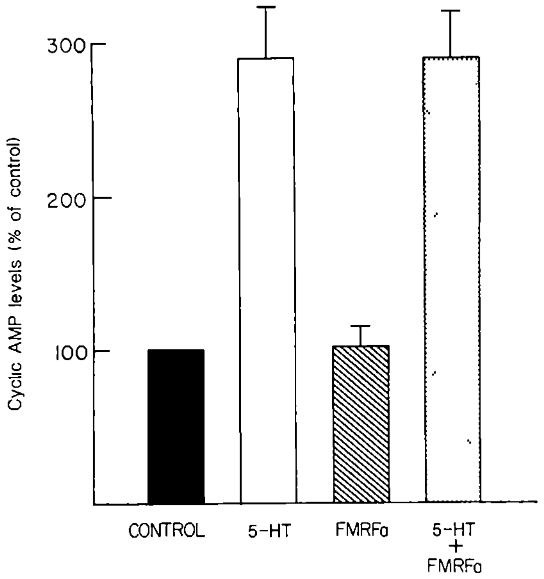

FIG. 2 Cyclic AMP levels in pleural sensory clusters after treatment with 5-HT or FMRFamide (FMRFa). Pleural sensory clusters were stimulated with 40 μM 5-HT for 2 min in the presence of 100 μM IBMX (1 min pre-incubation), or 10 μM FMRFamide with 100 μM IBMX for 1 min. Where 5-HT and FMRFamide were added together, 5-HT was added first for 1 min, then FMRFamide was added and the incubation continued for 1 min. Paired contralateral sensory clusters were used as controls and received no addition. Results shown are means ± s.e.m. for three separate experiments. Addition of IBMX alone cause no significant effect on cAMP levels when assayed at 3 min (control, 100%, IBMX, 79% ± 8%, $n=3$). Previous studies have demonstrated that certain agonists decrease cAMP levels independent of adenylyl cyclase inhibition, at the level of phosphodiesterase activation[9]. The necessity of performing our cAMP assays on cells treated with phosphodiesterase inhibitor precluded us from this directly as a possible mechanism contributing to the inhibitory override.

METHODS. *Aplysia californica* (100–220 g) were obtained from the Marine Biological Laboratories mariculture facility at Woods Hole, Massachusetts. Animals were anaesthetized by injection of approximately one-half of their body weight of isotonic $MgCl_2$. Ring ganglia (cerebral, pleural and pedal ganglia) were removed and pleural sensory neuron clusters, with underlying neuropil, were dissected free (see ref. 19). These bilaterally symmetrical clusters, of ~200 sensory neurons each, were kept as pairs from one animal. Each pair was used for a single experimental determination (assayed in triplicate), with one cluster serving as control and one as treated. This allowed us to perform intra-animal normalization and served to elimiate the inter-animal variability found for basal cAMP levels in *Aplysia* (see also ref. 19). The amount of protein in the left versus the right sensory cluster from one animal (~10 μg) was found to be highly consistent. Thus, comparing left versus right is equivalent to normalizing each sample to protein. Cyclic AMP was assayed using a radioimmunoassay kit (Amersham). Incubations were terminated by the addition of an ice-cold trichloroacetic acid solution to a final concentration of 10%. After 10 min on ice, samples were centrifuged, supernatants collected and ether-extracted, and cyclic AMP assayed. Results were calculated as the ratio of fmol cAMP for experimentals to fmol cAMP for controls. Control samples typically contained 50–75 fmol cAMP per sensory cell cluster.

(s.e.m. = 7.2, $n=5$) and was increased by 5-HT (presynaptic facilitation) to 229% of the control (s.e.m. = 20, $n=5$). When FMRFamide was applied in the presence of 5-HT, the facilitation of the synaptic potential was then overriden and the amplitude of the synaptic potential reduced to 55% of that of the control (s.e.m. = 12, $n=5$).

As expected from the single channel results, the override is also evident in the total membrane current (Fig. 1*b*). Under voltage clamp, application of FMRFamide (10 μM) alone produced an average increase in outward current of 0.23 ± 0.11 nA (±s.d., $n=4$, $V_m = -40$ mV). A mean decrease in outward current of 0.23 ± 0.12 nA ($n=4$) was caused by 5-HT (10 μM) alone. When FMRFamide was applied in the presence of 5-HT, however, the mean FMRFamide-induced current of 0.38 ± 0.10 ($n=4$) was then greater than the FMRFamide-induced current in the absence of 5-HT. FMRFamide therefore not only reverses the decrease in outward current produced by 5-HT, but increases the net current to a level similar to the peak outward current reached with FMRFamide alone. FMRFamide exerts a similar override in the decrease in outward current produced by a membrane-permeable analogue of cAMP (Fig. 1*b*). Thus, at all three levels—transmitter release, membrane current and single channel activity—FMRFamide overrides the action of 5-HT. These results demonstrate that FMRFamide has at least two qualitatively distinct effects in sensory neurons, an inhibitory action when acting on its own, and an overriding action that opposes the action of 5-HT.

How, therefore, does FMRFamide exert its overriding action?

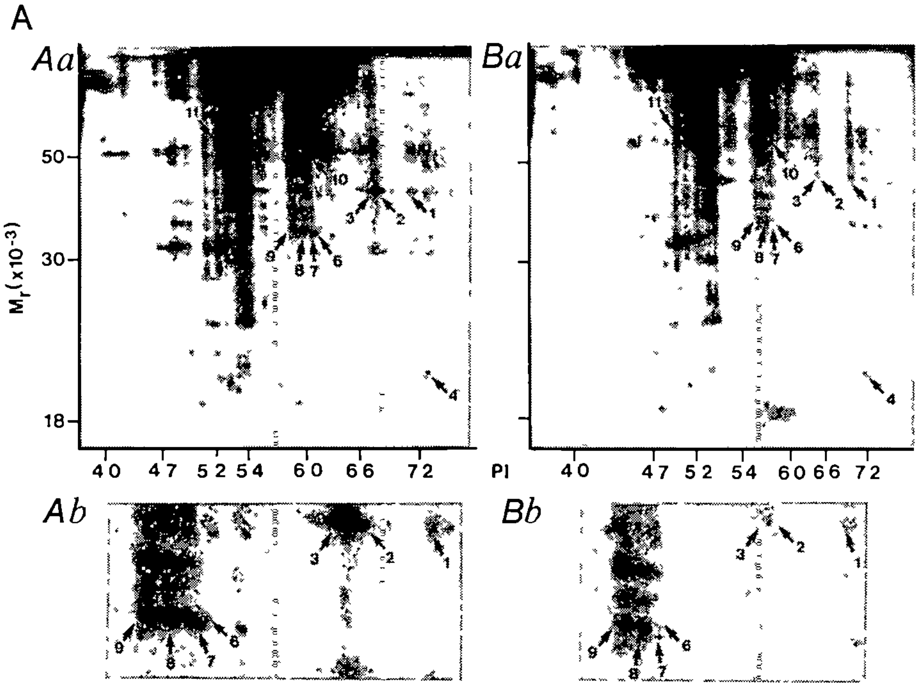

FIG. 3 *A* and *B*, Autoradiographs from contol *Aa* and FMRFamide (*Ba*) treated cells. Autoradiographs are of 2-D gels run on ^{32}P-labelled sensory clusters. Labelling of sensory clusters, 2-D electrophoresis and autoradiography was performed as previously described[20]. *Ab* and *Bb*, Expansion of the central regions of *Aa* and *Bb*. FMRFamide (10 μM) was present for 1 min. In additional experiments (data not shown), no losses of protein spots in response to FMRFamide (10 μM for 1 min) were observed in sensory neurons labelled for 24 h with [^{35}S]methionine (50 μCi per cluster), indicating that the loss of ^{32}P label was not due to a decrease in substrate protein mass.

Specifically, at which stage of the cAMP cascade does FMRFamide exert its antagonistic effect? Three sites of interaction seem possible. First, FMRFamide could override the cAMP cascade by inhibiting the adenylyl cyclase. Second, FMRFamide could stimulate phosphodiesterase activity thereby leading to an increase in the hydrolysis of cAMP (ref. 9). Third, FMRFamide, possibly acting through the metabolites of the lipoxygenase pathway[17], could act at a later stage in the cAMP cascade to reverse phosphorylation of the substrate proteins either by inhibiting cAMP-dependent protein kinase or by activating a phosphoprotein phosphatase. To test these ideas, we studied the interaction of the two cascades at the biochemical level by examining cAMP production and protein phosphorylation.

Although adenylyl cyclase inhibition cannot *per se* explain the antagonism by FMRFamide of the effects of the analogue of cAMP (ref. 15 and Fig. 1*b*), inhibition of the cAMP cascade could still be a contributory mechanism in the antagonism by FMRFamide of the action of 5-HT. We therefore tested the ability of FMRFamide to inhibit adenylyl cyclase by using a radioimmunoassay for cAMP levels in the presence of the phosphodiesterase inhibitor 3-isobutyl-1-methyl-xanthine (IBMX) in *Aplysia* pleural sensory neuron clusters (Fig. 2). 5-HT increased the level of cAMP in *Aplysia* sensory neurons, whereas FMRFamide had no effect, thus confirming previous findings (refs 18 and 19, and T. W. Abrams *et al.*, personal communication). Moreover, FMRFamide did not attenuate the increase in cAMP produced by 5-HT (in agreement with K. A. Ocorr, M. Tabata and J. H. Byrne, personal communication).

These results indicate that the interaction between 5-HT and FMRFamide must occur after the rise in cAMP concentration, perhaps at the level of the phosphorylation and dephosphorylation of substrate proteins. We have previously characterized the effects of 5-HT and cAMP on substrate phosphorylation in the sensory neurons by using an intact-cell protein phosphorylation assay based on quantitative two-dimensional gel autoradiography[20]. We have now used this assay to investigate the effects of FMRFamide on protein phosphorylation, and to search for possible sites of interaction between FMRFamide and the cAMP cascade.

We earlier found that, out of a total of 300–400 phosphoproteins in the sensory neurons resolved by two-dimensional gel electrophoresis[20], 5-HT and cAMP elicit an increase in phosphorylation of 17 proteins. By contrast, we found that FMRFamide elicits a decrease in protein phosphorylation (Figs 3 and 4). Thus, FMRFamide acting alone causes a decrease in the phosphorylation of a subset of 10 of the 17 proteins whose level of phosphorylation is increased by 5-HT or cAMP. No other phosphoproteins resolved on the gel were affected reproducibly. It is unlikely that the decrease in phosphorylation was caused by proteolysis, because autoradiographs from sensory neuron clusters labelled for 24 h with [^{35}S]methionine showed no significant loss of protein spots in response to FMRFamide.

Could a decrease in phosphorylation with FMRFamide contribute to the override of 5-HT's action? To address this question we examined the pattern of protein phosphorylation when FMRFamide was applied in the presence of 5-HT. We found that when FMRFamide is given in the presence of 5-HT it reverses the phosphorylation of all 17 proteins whose phosphorylation is increased in response to 5-HT (Fig. 4). Moreover, FMRFamide also decreased phosphorylation of proteins phosphorylated in response to application of a cAMP analogue. As the experiments with the cAMP analogue were done in the presence of the phosphodiesterase inhibitor IBMX, the decrease in phosphorylation cannot be explained by activation of a phosphodiesterase.

Recent evidence indicates that a single neurotransmitter can exert multiple physiological effects through separate biochemical pathways. Our previous experiments characterized two distinct actions of FMRFamide on S-channel function. Acting on its own, FMRFamide leads to an increase in S-channel open probability (P_o), with no change in the number of active S-channels. When applied in the presence of cAMP or 5-HT, however, FMRFamide also reopens S-channels closed by these agents, leading to an increase in the number of open S-channels in addition to the increase P_o. Our present results indicate that these two actions may be mediated by distinct biochemical mechanisms. The increase in P_o with FMRFamide has been shown to be a direct action of 12-lipoxygenase metabolites of arachidonic acid on the S-channel, independent of protein phosphorylation or dephosphorylation (refs 21, 28). Here we show that FMRFamide also decreases the level of resting protein phosphorylation and reverses the increase in phosphorylation in response to 5-HT and cAMP, thereby providing a probable mechanism for the override of the physiological action of 5-HT and cAMP.

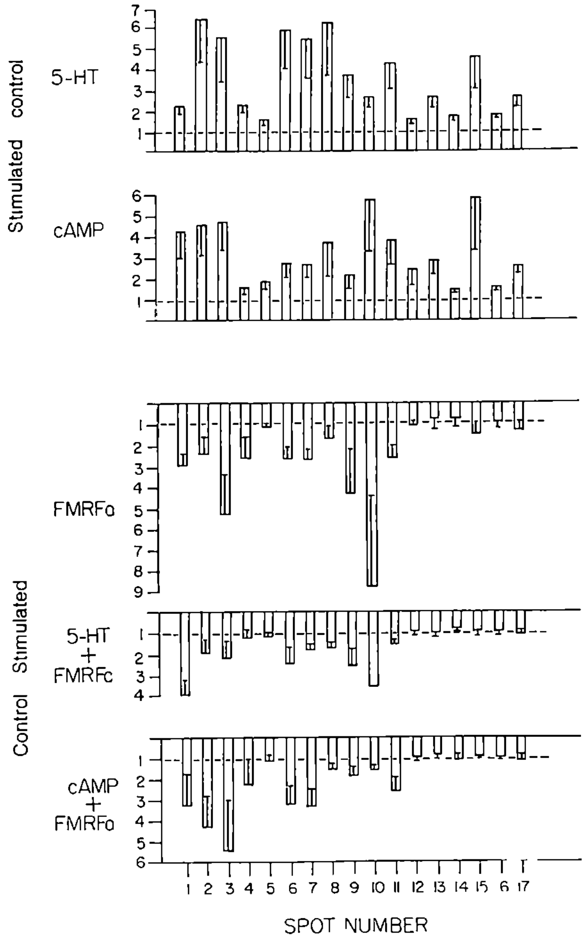

FIG. 4 Effects of various treatments on the phosphorylation of 17 selected proteins from *Aplysia* sensory neurons. Results shown are the means (±s.e.m.) of the ratios of stimulated:control for 5-HT (*n*=6) and cAMP analogue (*n*=7), and control:stimulated for FMRFamide [FMRFa, *n*=7), FMRFa with 5-HT (*n*=4), and FMRFamide with cAMP analogue (*n*=5). Of ~300–400 phosphoprotein spots per gel, only these 17 were found to reproducibly change because of the indicated treatments. Quantitative information for the ^{32}P content of control and stimulated samples was determined by densitometric scanning, and spots were matched and ratios were calculated using the PDQuest computer analysis system[20]. Treatments were 40 μM 5-HT for 2 min, or 100 μm 6-(4-chlorophenylthio)-cyclic AMP with 100 μM phosphodiesterase inhibitor (either IBMX or RO20-1724) for 10 min. Effects on protein phosphorylation were assayed at the end of the stimulus period. Where indicated FMRFamide (10 μM alone or in the presence of 5-HT or cAMP analogue with IBMX) was added 1 min before termination of the incubation. The results shown for 5-HT and cAMP analogue have been reported previously[20].

At present, we cannot distinguish whether this decrease in phosphorylation associated with the override in response to FMRFamide is due to kinase inhibition or phosphatase activation Nor do our experiments by themselves prove a causal link between the decrease in phosphorylation and the override Nonetheless, because the effects of 5-HT and cAMP on S-channel activity in the sensory neurons are mediated by cAMP-dependent phosphorylation, the decrease in phosphorylation with FMRFamide provides a plausible biochemical mechanism for the override

Receptor-mediated decreases in protein phosphorylation (by inhibition of the kinase or activation of a phosphatase) may prove to be a widespread mechanism of cell modulation[22] For example, although the most common mechanism for antagonizing the cAMP cascade is through inhibition of adenylyl cyclase, some mechanisms for antagonism are known to operate in the face of elevated cAMP levels (for reviews, see refs 23-25) Thus, in addition to our previous findings that FMRFamide opens S-channels, there is evidence that in smooth muscle cells acetylcholine can override the effects of cAMP on M-current[26], and in pancreatic islet cells that α_2-adrenergic agonists can inhibit the release of insulin induced by cAMP[27] These examples indicate that a receptor-mediated decrease in phosphorylation could serve in other cell systems to overcome the actions of the cAMP-dependent kinase, or even of other second messenger-dependent kinases □

T-CELL accessory molecules, particularly CD4 and CD8, seem to be involved in the control of T-cell activation by antigen. Precisely how such molecules operate is not fully understood, but evidence to date suggests a dual role, as receptors binding ligands on stimulator cells[1,2] and by direct or indirect involvement in intracellular signalling events[3-5] In mouse, truncated 'tailless' CD8 molecules occur naturally (CD8α' polypeptides) and although they are expressed on the surface of thymocytes, they are not expressed on the surface of mature T cells[6] In this study, we show that truncated CD8 molecules are impaired in their ability to interact with the protein tyrosine kinase, p56^{lck}, and have decreased ability to restore immune responsiveness *in vitro* Our data support a dual function for CD8 molecules correlated with expression of external domains and cytoplasmic domains, respectively. Both functions appear to be critical for a competent immune system *in vivo*

We have previously shown that control of surface expression of tailless CD8α' polypeptides in mature peripheral T cells is at the level of protein transport[7] That mature cells should be so stringent in excluding CD8α' chain expression on the cell surface indicates that expression of these tailless molecules may have a negative influence We tested this directly by transfecting individual complementary DNAs encoding CD8α or α' polypeptides into a mouse T-cell hybridoma, DC27 10, which has been transfected with genes encoding the T-cell receptor (TCR) α and β chains specific for class I H-2K^b molecules This hybridoma provides a convenient system in which to assay CD8 function as the transfectant is incapable of responding to antigen in the absence of CD8 molecules, although it will respond to the anti-TCR clonotype antibody, Désiré-1 (ref 8) We selected variants of DC27 10 which lack expression of endogenous CD4 molecules before transfecting CD8 constructs Both α and α' polypeptides can be expressed stably on the surface of this hybridoma in the absence of the CD8β (Ly-3) product (Fig 1*a*) The molecules are expressed as disulphide-bonded homodimers (data not shown) Several individual transfectants were analysed for their ability to respond to anti-clonotypic antibody bound to plastic (Fig 1*b*) and antigen, namely K^b-transfected L cells (Fig 1*c*) Expression of the truncated CD8α' chain is sufficient to permit some restoration of the antigen response Cells expressing the full length CD8α polypeptide, however, respond much better This is particularly apparent if you directly compare a pair of CD8α and α' transfectants which express equivalent but lower levels of both transfected CD8 molecules and T-cell receptors Transfectants a2 and b8, for example, express less CD8 (Fig 1*a*) and respond less well to Désiré-1 antibody (Fig 1*b*) The CD8α transfectant, b8, responds well to antigen in contrast to the CD8α' transfectant, a2, which is completely unresponsive Comparison of transfectants expressing more CD8 and with higher responses to Désiré-1, a1 and b8 2 (Fig 1*a*, *b*), shows that although the CD8α' expressing cells can make some antigen response it is much weaker than that obtained from the CD8α expressing cells (Fig 1*c*) Indeed the antigen response of the brighter CD8α' expressing transfectant is not even as good as that of the duller CD8α expressing transfectant (compare a1 with b8) The fact that some restoration of response can occur in transfectants expressing CD8α' chains indicates that the external domain alone does play a role in the antigen response

Transfectants expressing hybrid CD4/CD8 molecules as described in Fig 3, were tested for response to anti-clonotypic antibody Desire-1 (10 μg/ml) 1×10^5 K^b expressing L cells per well or 1×10^6 C57B1/6 anti-thy-1 and complement treated spleen cells per well, as described in Fig 1 Results are expressed as units of interleukin-2 (IL-2) extrapolated from titrating the supernatants on CTLL indicator cells (see Fig 1)

of these accessory molecules in T-cell signalling occurs indirectly through association with this protein tyrosine kinase One possible explanation for the decreased efficacy of the tailless CD8α' chains would be an inability to associate with $p56^{lck}$, and thus participate in intracellular phosphorylation events We tested this by immunoprecipitating CD8α and α' transfectants with anti-$p56^{lck}$ or anti-CD8 antibodies and immunoblotting to assess the presence of co-precipitating $p56^{lck}$ Figure 2*a* clearly demonstrates that in contrast to CD8α chains, CD8α' chains are not associated with $p56^{lck}$ The CD8 molecules on the surface of peripheral T cells are expressed normally as αβ heterodimers, the products of two separate genes (Ly-2 and Ly-3 in mouse) The CD8β chain has a 19 amino-acid cytoplasmic tail and could potentially associate with $p56^{lck}$ We found, however, that this was not the case when we examined cells co-transfected with either CD8α plus β or CD8α' plus β complementary DNA These transfectants show cell-surface expression of CD8αβ or α'β heterodimers respectively, but only the transfectants expressing CD8αβ show association with $p56^{lck}$ (Fig 2*b*) The CD8 α'β heterodimers are present intracellularly in mature murine T cells but are not expressed on the cell surface (R Z, unpublished data) The demonstration that $p56^{lck}$ cannot associate with this heterodimer indicates that expression of molecules capable of $p56^{lck}$ association is critical for an optimally func-

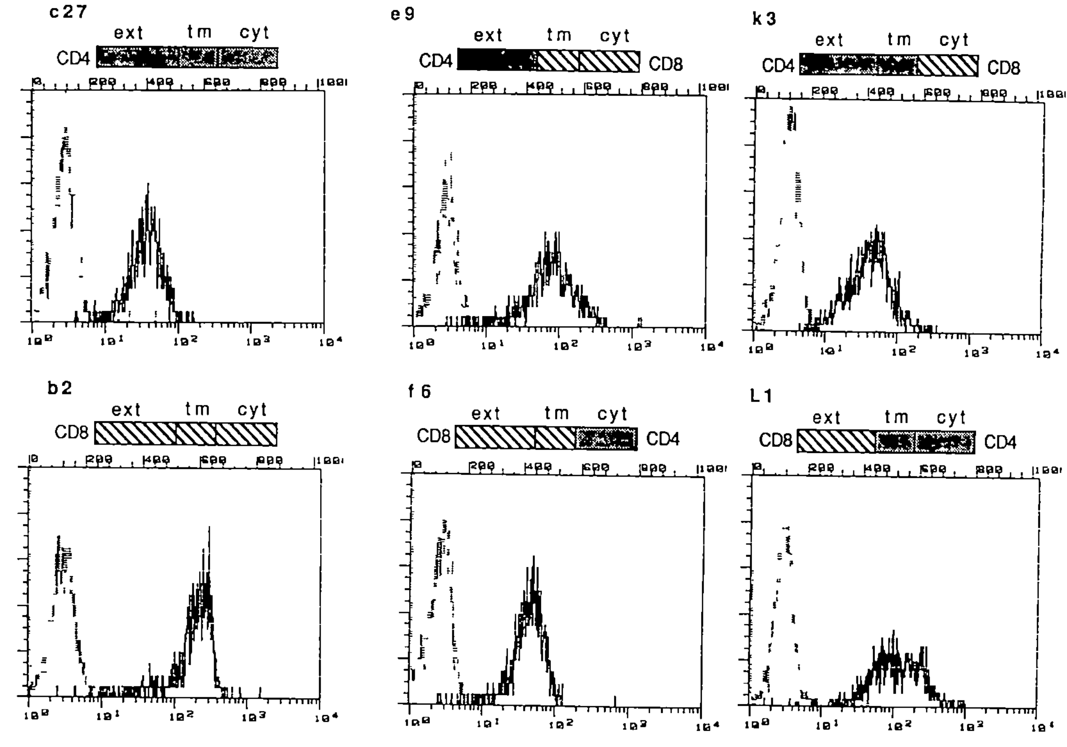

FIG 3 Expression of transfected CD4/CD8 hybrid molecules DC27 10 hybridoma cells were transfected with hybrid cDNA molecules encoding assorted CD4 (filled boxes) and CD8 (dashed boxes) extracellular (ext) transmembrane (tm) and cytoplasmic (cyt) domains, as indicated over each FACS profile Clones expressing CD4 extracellularly, c27, e9 and k3, were stained with FITC-labelled goat anti-rat antibodies alone (dashed profiles) and anti-CD4 (GK1 5) plus FITC-labelled goat anti-rat antibodies (solid profiles) Clones expressing CD8 extracellularly, b2, f6, and L1, were stained with FITC-labelled goat anti-rat antibodies alone (dashed profiles) and anti-CD8 (YTS169 4) plus FITC-labelled goat anti-rat antibodies (solid profiles) Fluorescence intensity, horizontal scale

METHODS Hybrid cDNA molecules were constructed by introducing complementary restriction enzyme sites (*Eco* RV at the extracellular/transmembrane junction, or a *Bst* XII site at the transmembrane/cytoplasmic junction) into CD8 and CD4 cDNAs using site-specific mutagenesis, and then swapping the domains between them Oligonucleotides were designed to minimize amino-acid changes and to maintain the correct reading frame when introducing the restriction enzyme site, although in some cases conservative changes did result No differences were observed in the functions of native and mutated but 'unshuffled' CD4 and CD8 molecules The junctional amino-acid sequences for external/transmembrane domain shuffles were as follows native and mutated CD8-FACD/IYIW , native CD4- VNQT/VFLA , mutated CD4 (transfectant c27)- VNQTD/ILA , ext CD4/tm + cyt CD8 (transfectant e9)- NQTD/IYIW , ext CD8/tm + cyt CD4 (transfectant f6)- FACD/ILA Junctional amino-acid sequences for transmembrane/cytoplasmic domain shuffles were native CD8-LICY/HRSR , native CD4- LCCV/RCRH , mutated CD8 (transfectant b2)- LICY/ARSR , ext + tm CD4/cyt CD8 (transfectant k3)-LCCA/RSRL , ext + tm CD8/cyt CD4 (transfectant L1)- LICYA/RCRH Hybrid cDNAs were subcloned into the β-actin expression vector and transfected as described in Fig 1 tional immune system *in vivo* Given that the α chain alone is able to restore antigen responsiveness, it is not clear why there is a preference for expression CD8$\alpha\beta$ heterodimers rather than CD8$\alpha\alpha$ homodimers on mature T cells It is possible that the CD8β chain has a separate role during the development of $\alpha\beta$ TCR bearing cells in the thymus This would correlate with the observation that intra-epithelial lymphocytes, which are mainly $\gamma\delta$TCR bearing cells[13], predominantly express CD8α homodimers on their surface[14]

The expression of CD4 or CD8 accessory molecules by T cells correlates strongly with whether T cells are restricted by class II or class I MHC molecules[15] Studies in transgenic mice have shown that T cells expressing class I restricted TCR α and β transgenes favour the co-expression of CD8 molecules[16,17] Although this bias may be generated by co-selection of receptor and accessory molecules binding the same class I MHC structure, it is also possible that selection occurs based on preferential interactions between particular TCR and accessory molecule transmembrane or intra-cellular domains We examined this possibility by constructing hybrid cDNA constructs between CD4 and CD8 genes which encode the extra-cellular portion of one together with either the cytoplasmic domain, or the transmembrane plus cytoplasmic domain of the other It was previously shown that expression of CD4 molecules by DC27 10 is insufficient to restore the response to K^b even when stimulator cells express both class II and class I molecules[8] If there is an interaction of the anti-K^b TCR with CD8 in the intra-cellular domains then the hybrids expressing CD4 externally and CD8 internally should be capable of responding to antigen

Transfectants expressing all combinations of hybrid CD4/CD8 molecules were isolated and stained with appropriate monoclonal antibodies (Fig 3) All of the hybrid constructs were expressed stably on the cell surface Immunoprecipitation of these molecules (data not shown) revealed that all constructs expressing CD4 externally were monomers, in contrast to constructs expressing CD8α externally, which were expressed as disulphide bonded homodimers This indicates that interactions between CD8 external domains dictate that this molecule is expressed normally as a dimer Transfectants which gave similar responses to anti-clonotypic antibodies were assayed for their ability to respond to antigen (Table 1) As K^b transfected L cells do not express class II MHC molecules, hybrid constructs expressing CD4 external domains were assayed on H-2K^b spleen cells Despite the presence of the CD4 ligand on the stimulator cells, expression of these hybrid molecules was insufficient to restore antigen response By contrast, transfectants expressing hybrid molecules containing CD8α external domains, whether in combination with CD4 cytoplasmic domains or CD4 transmembrane and cytoplasmic domains, functioned extremely efficiently The latter constructs were at least as effective as native CD8α homodimers in conferring responsiveness to antigen Thus, there does not appear to be preferential association of transmembrane or intracytoplasmic domains of CD8 with a class I specific cell receptor

These data demonstrate an incremental restoration of full antigen responsiveness conferred by transfected CD8 molecules The first step is the progress from complete absence to limited responsiveness conferred by high level expression of CD8 extracellular domains in combination with sufficient expression of TCRs This property can be ascribed to increased avidity stabilizing the interaction between the T cell and the antigen presenting cell It is interesting to note that in contrast to the experiments reported by Gay *et al*[18], our experimental system has an absolute requirement for both the TCR and accessory molecules to recognize class I MHC The Désiré-1 TCR has low affinity for antigen[19] and may only be stabilized by CD8 external domains binding to the same class I molecules as the TCR This requirement may not be so obvious for higher affinity TCRs

The second increment by which CD8 influences responsiveness relates to the presence of the cytoplasmic domain and correlates with the ability to associate with p56^{lck} This association has been demonstrated for both CD4 and CD8 molecules and can explain why CD4 intracellular domains are efficient substitutes for CD8 intracellular domains These results are in contrast to hybrid CD8 molecules with class I cytoplasmic domains which are only as efficient as CD8α' chains in restoring responsiveness (B Malissen, personal communication) □

Genetic imprinting suggested by maternal heterodisomy in non-deletion Prader-Willi syndrome

PRADER-WILLI syndrome (PWS) is the most common form of dysmorphic genetic obesity associated with mental retardation[1,2] About 60% of cases have a cytological deletion of chromosome 15q11q13 (refs 2, 3) These deletions occur *de novo* exclusively on the paternal chromosome[4,5]. By contrast, Angelman syndrome (AS) is a very different clinical disorder and is also associated with deletions of region 15q11q13 (refs 6–8), indistinguishable from those in PWS[6,8] except that they occur *de novo* on the maternal chromosome[6] The parental origin of the affected chromosomes 15 in these disorders could, therefore, be a contributory factor in determining their clinical phenotypes. We have now used

cloned DNA markers specific for the 15q11q13 subregion[5,9,10] to determine the parental origin of chromosome 15 in PWS individuals not having cytogenetic deletions, these individuals account for almost all of the remaining 40% of PWS cases Probands in two families displayed maternal uniparental disomy for chromosome 15q11q13 This is the first demonstration that maternal heterodisomy—the presence of two different chromosome 15s derived from the mother—can be associated with a human genetic disease. The absence of a paternal contribution of genes in region 15q11q13, as found in PWS deletion cases[4,5], rather than a mutation in a specific gene(s) in this region may result in expression of the clinical phenotype Thus, we conclude that a gene or genes in region 15q11q13 must be inherited from each parent for normal human development.

Given the unusual parental origins of deletion chromosomes associated with PWS and AS, we attempted to determine the parental origins of chromosomes 15 in non-deletion cases of PWS For each family, we performed restriction fragment length polymorphism (RFLP) analyses with nine RFLPs at seven loci specific for proximal chromosome 15q (refs 5, 11) The first family that we studied has a proband with a phenotype typical of PWS (refs 1, 2), that is, hypotonia and growth delay in infancy, short stature, hyperphagia with consequent obesity, small hands and feet, hypogonadism and mild mental retardation This family also displays inheritance of a balanced robertsonian translocation, t(13, 15) (Fig 1*a*) Association of this translocation with the phenotype of PWS is highly unlikely because unaffected maternal relatives carry the same balanced translocation (Fig 1*a*), and the translocation breakpoint is at the centromere of chromosome 15, some distance from the critical region at 15q11q13 In this family the PWS proband (PWS1) had inherited two maternal alleles but no paternal allele (Fig 1*b*) specific for probe 3-21, which maps to the region absent in PWS patients with deletions[5,9 10] The 8 2-kilobase (kb) *Taq*I fragment detected by probe 3-21 (Fig 1*b*) is shared by the three individuals (PWS1, his mother M1, and half-sister) carrying the t(13, 15) translocation and is, therefore, a marker for this chromosome The 8 9-kb *Taq*I fragment which hybridized to probe 3-21 is present in both PWS1 and his mother and is not present in the other individuals of the family, clearly indicating the maternal derivation of the non-translocated chromosome 15 in PWS1, at least for region 15q11q13 surrounding the probe 3-21 locus We confirmed and extended this result by using CMW-1, a multiallelic DNA marker[11] that maps distal to the region of deletions associated with PWS (unpublished result) The segregation pattern again showed two maternal alleles but no paternal allele for the proband (Fig 1*c*) We excluded the possibility of non-paternity by analysis with a cloned fragment (3'HVR) from the 3' hypervariable region of the α-globin locus on chromosome 16 (ref 12, Fig 1*d*)

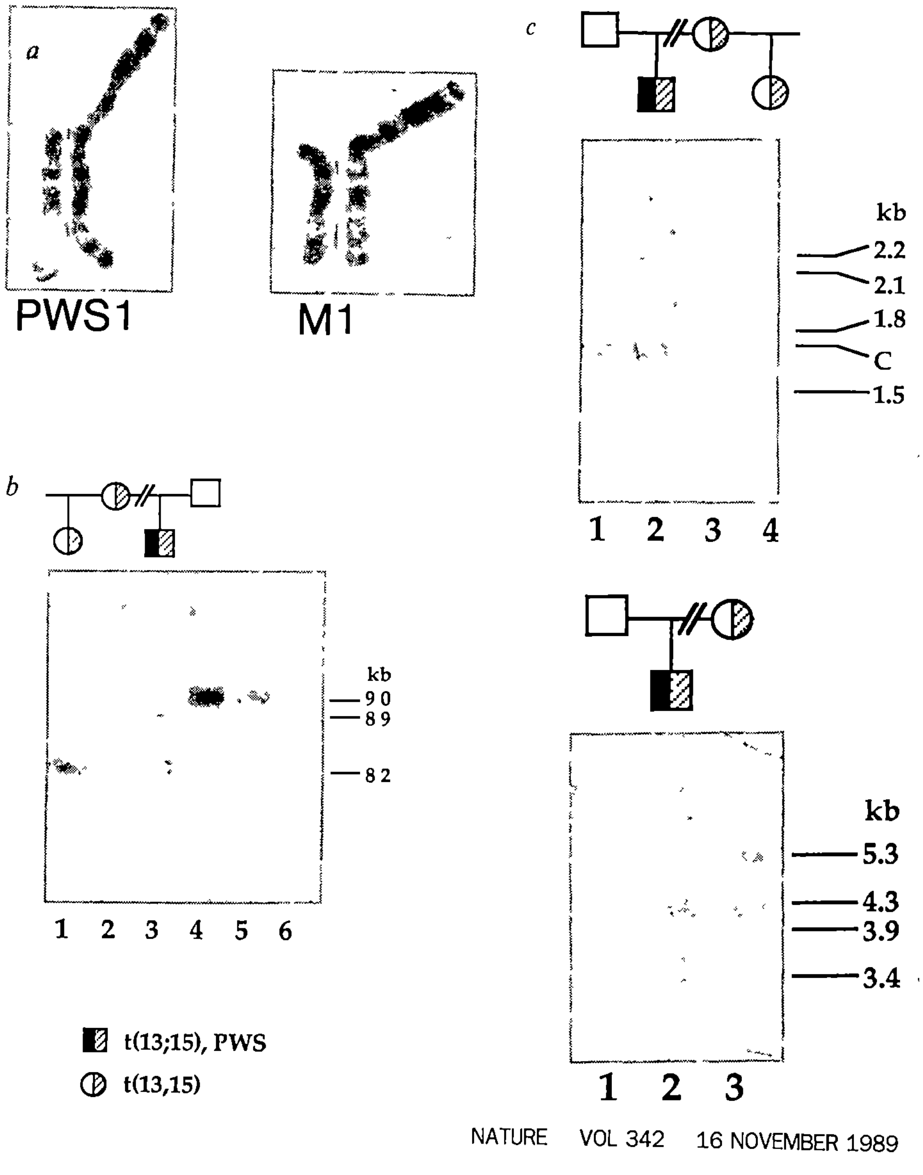

FIG 1 Maternal uniparental disomy in a PWS patient with a balanced Robertsonian translocation *a*, Normal chromosome 15 and translocated homologue from patient PWS1 (left) and his mother M1 (right) Other unaffected maternal relatives, including the half-sister of PWS1 carry the same balanced chromosome 13q15q robertsonian translocation *b*, Maternal origin of the two chromosomes 15 in patient PWS1 An 8 2-kb *Taq*I allele of probe 3-21 (D15S10) is shared by PWS1 (lane 3), his mother M1 (lane 2) and half-sister (lane 1), whereas an 8 9-kb band is shared by PWS1 and M1 PWS1 does not inherit a 9 0-kb paternal allele (F1, lane 4) Mixing experiments (lane 5, PWS1 and F1, lane 6, M1 and F1) show the identity of the three alleles in this new RFLP system *c*, Presence of two maternal alleles only for CMW-1 (D15S24) in PWS1 PWS1 (lane 2) shares two *Taq*I restriction fragments, of 2 1 and 2 2 kb, with M1 (lane 3) but has neither of the 1 5- or 1 8-kb paternal alleles (F1, lane 1) The half-sister (lane 4) displays the maternal 2.1-kb and a 2 15-kb allele The band at 1 7 kb is constant, C *d*, Exclusion of non-paternity for PWS1 *Pvu*II-digested DNA was hybridized to the α-globin 3'HVR marker (D16S85), one of the most highly polymorphic markers in the human genome[12] PWS1 (lane 2) shows mendelian inheritance of one paternal 3 9-kb allele (lane 1) and one maternal 4 3-kb allele (lane 3) The half-sister inherits her mother's 5 3-kb allele (result not shown)

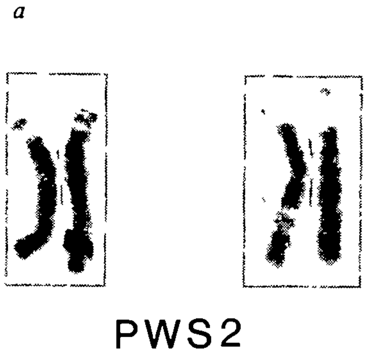
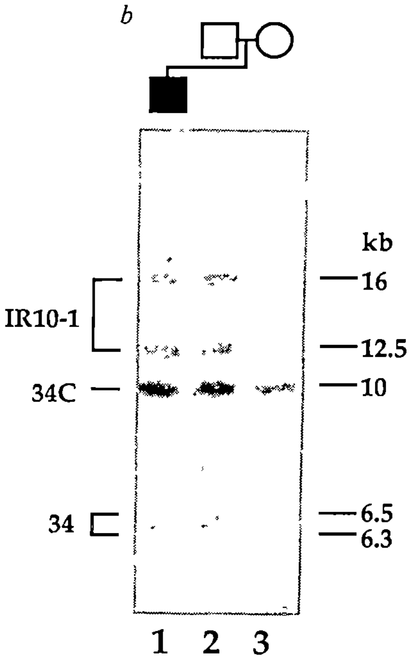
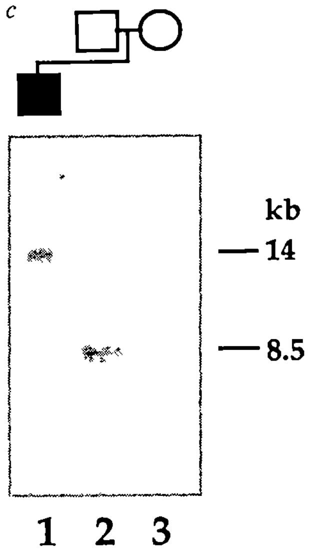
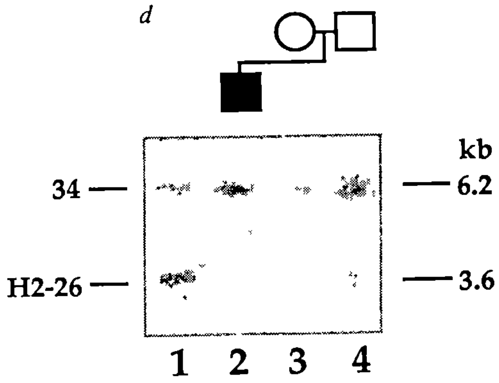
METHODS DNA was isolated from blood and/or cell lines from each individual as described previously[5] Hybridizations were carried out as previously described[5] High-resolution chromosome analyses from peripheral blood lymphocytes[29] were performed by Giemsa-trypsin banding[30]

The proband (PWS2) of the second family also has classical PWS (refs 13, 14) Cytogenetically, PWS2 has two intact chromosome 15s (Fig 2*a*) We demonstrated the lack of paternal alleles for two loci by haplotype analysis (Fig 2*b*, *c*) With probe 34, the father is homozygous for 6 5 kb alleles, whereas the mother is homozygous for 6 3 kb alleles (Fig 2*b*) For the proband, we found only a 6 3-kb band (Fig 2*b*), consistent with the maternal origin of both cytogenetically normal chromosomes 15 Likewise, only maternal alleles specific for probe IR39d had been inherited (Fig 2*c*) By dosage analyses we demonstrated that PWS2 has two copies of each of these maternally derived alleles (Fig 2*d* and results not shown), indicating that loci detected by probes 34 and IR39d had not been deleted These two loci are flanked by loci detected by probe IR4-3R (results not shown) and probe IR10-1, respectively, (Fig 2*b*) that are heterozygous in the proband To rule out the possibility of a submicroscopic deletion, we analysed the long-range structure of the 15q11q13 region by pulsed-field gel electrophoresis (PFGE) This showed that probe IR4-3R and probe 34 detect the same large unaltered 2,500-kb *Not*I fragment in PWS2 (Fig 3), which provides strong evidence that the absence of a paternal allele specific for probe 34 does not represent a microdeletion Furthermore, we detected a band corresponding to a fragment of the same size (2,500 kb) in the mother, despite differential methylation leading to partial









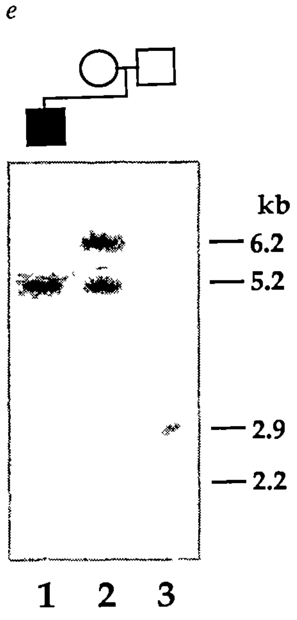


FIG 2 Maternal uniparental disomy in a PWS patient with apparently normal chromosomes 15 *a*, Two pairs of intact chromosomes 15 of PWS2 Previous reports have indicated these chromosomes as being intact[13] or deleted 15q (ref 14), in the deletion report a polymorphic shortening of 15q11 (ref 7) was probably detected, because we show here at a higher level of resolution that the chromosomes are intact *b*, Maternal origin of the two chromosomes 15 in PWS2 DNA was digested with *Sca*I PWS2 (lane 1) inherits a maternal 6 3-kb allele (lane 3) but no paternal 6 5-kb allele (lane 2) for probe 34 (D15S9) Each individual is heterozygous for IR10-1 (D15S12, 16- and 12 5-kb alleles), which is from the same 15q11q13 region as probe 34 (ref 10) The band at 10 kb is constant, C, for probe 34 in all individuals[5] *c*, PWS2 inherits maternal alleles only for probe IR39d (D15S18) DNA was digested with *Sac*I and hybridized with the 15q11q13-specific probe IR39d PWS2 (lane 1) inherits his mother's (lane 3) 14-kb alleles and not his father's (lane 2) 8 5-kb alleles *d*, Two copies of the maternal allele for probe 34 in PWS2 *Hin*dIII-digested DNAs from PWS2 (lane 2), mother M2 (lane 3), father F2 (lane 4) and a PWS patient displaying both a cytological and molecular deletion of 15q11q13 (ref 5, lane 1, HS2) were hybridized simultaneously with probes 34 and H2-26 (D13S28)[31] Probe H2-26 from chromosome 13 serves as a reference for quantitation of copy number[10] Probe 34 shows a reduced hybridization intensity relative to H2-26 only in HS2, which is consistent with a deletion of 15q11q13 in this individual No reduction in probe 34 hybridization intensity is observed in PWS2 or his parents To quantitate the intensity of the hybridization bands, the autoradiogram was scanned with an LKB Ultrascan XL laser densitometer (Pharmacia LKB Biotechnology) The area ratio of the probe 34 to probe H2-26 peaks was calculated for each lane The number of copies of probe 34 per genome was obtained by setting the ratio in lane 3 (M2, mother) to 2 and normalizing the values in the other lanes to this value The number of copies of probe 34 per genome determined by this method were 1 0 in lane 1 (the HS2 deletion), 1 8 in lane 2 (PWS2) and 2 2 in lane 4 (F2, father) *e*, Exclusion of non-paternity for PWS2 One maternal 5 2-kb (lane 2) and one paternal 2 9-kb (lane 3) *Pvu*II allele are inherited by PWS2 (lane 1) for the 3'HVR

METHODS DNA and cytogenetic studies were as for Fig 1 Probe IR39d is a subclone of IR39 (ref 10), which lacks repetitive sequences PWS2 has been described before as patient number 5 (ref 14) and patient number 31 (ref 13)

*Not*I digestion in this region of the genome (Fig 3) and in other normal individuals (results not shown) We again excluded the possibility of non-paternity using the 3′HVR fragment, which detected an entirely different set of alleles in the PWS2 family (Fig 2*e*) from those that it detected in the PWS1 family (Fig 1*d*)

The results presented here indicate that both PWS probands inherited two different, intact chromosome 15q11q13 regions from their mothers Maternal heterodisomy—a newly defined form of uniparental disomy[15,16]—for at least the critical region of chromosome 15, could thus have an aetiological role in PWS The extent of disomy remains to be determined by genetic analysis with other markers The disomy extends beyond the PWS critical region identified from deletion studies because locus CMW-1, which maps distal to the deletion region, is disomic in PWS1 Several predictions can be made about an association between uniparental disomy and the aetiology of PWS First, there should be no chromosome deletion, as is shown in this study by using both cytogenetic and molecular genetic techniques Additional PFGE mapping data for PWS1 and PWS2 (Fig 3 legend) confirmed that a large part (4–5 megabases) of the 15q11q13 region is intact in these two patients Second, there should be no specific gene mutation Although point mutations cannot be ruled out until the gene(s) responsible for PWS are isolated, these seem unlikely because each case displays two independent maternal contributions to region 15q11q13 and the disorder is genetically dominant, which would rule out mechanisms such as the uncovering of a recessive mutation Finally, the frequency of maternal disomy should be high in PWS patients with normal chromosomes Consistent with this prediction, our preliminary data on four additional families strongly indicates that all of the PWS patients show maternal uniparental disomy

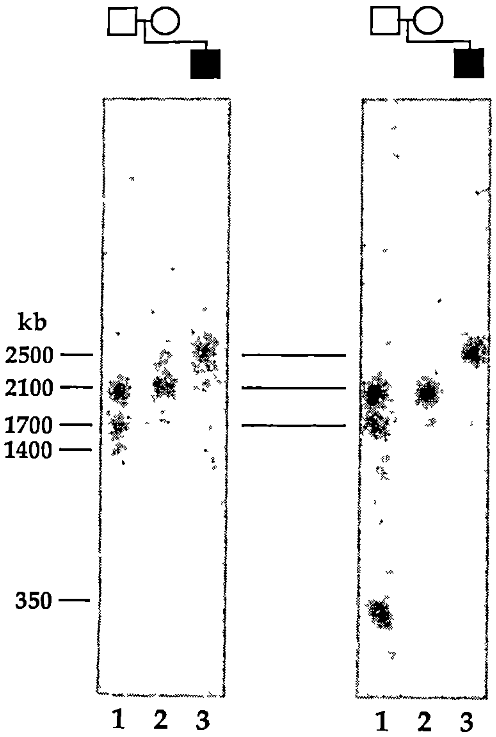

FIG 3 PFGE provides evidence for the lack of a submicroscopic deletion in PWS patients with uniparental disomy *Not*I fragments are shown for probes IR4-3R (D15S11) (left) and 34 (right) in PWS2 (lane 3), M2 (lane 2) and F2 (lane 1) Multiple bands are indicative of partial cleavage at restriction sites when CpG is methylated[32] and a similar pattern of multiple bands has been observed in other normal controls (results not shown) PWS2 shares a normal 2,500-kb band with his mother, although in the latter this results from partial digestion at a *Not*I site in this region of the genome The same 2,500-kb band has been detected in other normal individuals The larger three fragments are common to probes IR4-3R, 189-1 (results not shown) and 34, showing that these loci are closely linked in region 15q11q13 These probes and a 1,300-kb fragment detected with probes 3-21 and IR10-1 (unpublished data) are deleted in all PWS[10] and AS[6] patients with cytological deletions Additional PFGE analysis (results not shown) also indicates that PWS2 displays PFGE restriction fragments of normal size for IR10-1 in a *Not*I digest (1,300 kb) and for IR39d in a *Bss*HII digest (250 kb) PWS1 also seems to be intact for the probe 34 and 3-21 loci because the restriction fragments detected using *Not*I and *Bss*HII are unaltered compared with those of normal individuals

METHODS PFGE analyses were performed as described previously[33] using a modification of techniques for DNA preparation and digestion in agarose blocks[34] Electrophoresis was performed in 0 8% agarose in TBE (89 mM Tris buffer, pH 8 0, 89 mM boric acid, 2 mM EDTA) at 22 °C and was divided into three 48-h intervals during which the forward polarity pulse durations were varied from 75–600 s, 600–2,500 s and 2,500–3,000 s and field intensities were set at +2, +1 7 and +1 3 V cm^{-1}, respectively The ratios of the duration and intensity of the inverse polarity pulse relative to the forward were 0 4 and 0 5, respectively

It seems that the clinical phenotype of the two PWS probands arises from the absence of a paternal contribution to region 15q11q13, rather than from a specific gene mutation This implies functional differences in alleles of a gene or genes from this region of the genome that depend on the sex of the transmitting parent (genetic imprinting[18-21]) Under this scheme, normal human development would require genetic input from both parents, whereas the absence of a paternal contribution to region 15q11q13, whether by paternal deletion[4,5] or maternal uniparental disomy (as demonstrated here), would result in PWS Consistent with this hypothesis is our recent finding of differential transmission of parental alleles in PWS and AS (ref 6) It is conceivable, therefore, that the absence of a maternal contribution to the same 15q11q13 region could result in a different disorder, AS

Experimental evidence for genetic imprinting has been largely restricted to the mouse in which a requirement for a contribution of both the maternal and paternal genome for normal development has been demonstrated[18-22] Transgenic studies have provided preliminary evidence that the chromatin alteration involved in the differential modification and expression of parental alleles is DNA methylation[18-22], a process also associated with transcriptional regulation of gene activity[23] In humans, evidence of a developmental requirement for both parental genomes is provided by the finding that only the paternal genome is present in complete hydatidiform moles[24] Furthermore, differential transmission of parental alleles in several disorders such as Huntington's chorea[18,25], and somatic changes in childhood tumours such as Wilms tumour, osteosarcoma (reviewed in ref 26) and rhabdomyosarcoma[27] could involve genome imprinting Growth failure in two individuals with isodisomy[15] for chromosome 7 (refs 16, 28) could indicate genetic imprinting[16], although the aetiology of cystic fibrosis (CF) in these patients is homozygosity for a mutant CF allele inherited from the mother[16 28]

In conclusion, the association of PWS with maternal uniparental disomy for region 15q11q13 implicates a role for genetic imprinting in the aetiology of the PWS phenotype Similar phenomena could contribute to other clinical syndromes Isolation of the gene(s) responsible for PWS and other disorders in which genetic imprinting plays a part might be possible by identifying a gene that shows a differential modification of its parental alleles Our findings for PWS represent a step towards understanding the developmental basis of this common human genetic disorder ☐

Requirement for integrins during *Drosophila* wing development

Danny L. Brower & Sharon M. Jaffe

Department of Molecular and Cellular Biology, Biosciences West Building, University of Arizona, Tucson, Arizona 85721, USA

THE position-specific (PS) integrins of *Drosophila*[1,2] are highly homologous to vertebrate integrins[3–5], most of which are cell-surface receptors for extracellular matrix components[6,7]. Integrins are heterodimers, each consisting of noncovalently associated α- and β-subunits. As for the subfamilies of vertebrate integrins, the same β-subunit is found in both *Drosophila* PS integrins, combined with a specific α-subunit to generate either a complete functional PS1 or PS2 integrin[1,5,8]. Both α- and β-subunits are large transmembrane proteins (relative molecular masses >100,000). Either one or both of these two PS integrins are expressed in most fly tissues during development. A particularly intriguing pattern of expression is found in the mature wing imaginal disc, where the PS1 integrin is expressed primarily on the presumptive dorsal wing epithelium, and the PS2 integrin is found almost exclusively on the ventral epithelium[1]. Immediately after pupariation, the central wing pouch evaginates, folding along its centre to appose the epithelia that will secrete the dorsal and ventral surfaces of the adult wing blade[9]. Here we report the results of a genetic analysis indicating that both of the PS integrins are required to maintain the close apposition of the dorsal and ventral wing epithelia during morphogenesis. Also, we conclude that the integrins are not necessary for the maintenance of the cell lineage restriction between the two presumptive wing surfaces in the developing imaginal disc[10–12].

The α-subunit of the PS2 integrin seems to be encoded by the *inflated* (*if*) locus on the X chromosome[13], and null mutations at *if* cause embryonic lethality (M. Wilcox, A. DiAntonio and M. Leptin, manuscript submitted; see also Fig. 2 legend). We examined if^3 mutant larval tissues by using monoclonal antibodies directed against the PS integrins (anti-PS antibodies), and our results suggest that the if^3 allele is a regulatory mutation at the locus. Homozygous if^3 late third-instar larvae (just before pupariation and disc evagination) had apparently normal levels of PS2 integrin on most tissues (for example, muscles, salivary glands), but displayed greatly reduced levels of integrin on the surfaces of some imaginal disc cells (Fig. 1*b*). Specifically, there was relatively little PS2 integrin α-subunit in the ventral region of the wing pouch; these cells normally express the protein at very high levels. PS2 integrin expression was not so severely reduced in other regions of the disc, such as the peripodial membrane. The expression of the PS1 integrin in the wing disc seemed to be unaffected by if^3 (not shown).

Although all of the mutant wing discs examined were clearly affected, there was variability in the extent of PS2 integrin reduction (for example, Fig. 1*b*, *c*). In the wing pouch, mutant discs typically stained at higher levels anteriorly, and often displayed significant levels of staining with anti-PS2 antibody dorsally (Fig. 1*c*). Similar antero-posterior asymmetry and dorsal staining are characteristic of wild-type PS2 integrin expression in mid-third instar discs[14], about 24 h before pupariation. It is interesting that the pattern of PS2 integrin expression in if^3 discs seemed relatively normal at the mid-third larval instar (not shown), and it is possible that this allele simply does not allow the cells of the pouch to progress to the more mature pattern of expression.

Adult flies bearing the if^3 allele display wing blisters, in which the dorsal and ventral surfaces of the wing blade are separated[13]. We found that the penetrance and expressivity of the if^3 blisters were variable (Fig. 2); this is not surprising in light of the variability of the immunofluorescence results. Nonetheless, these data indicate that the PS2 integrin is important for maintaining the close apposition of the dorsal and ventral epithelia during morphogenesis of the adult wing.

That this is the case was confirmed by clonal analysis studies[15] of flies with mutations in the *myospheroid* gene (*mys*). The *mys* locus encodes the common PS integrin β-subunit[4,5], so null mutations at this locus would be expected to eliminate both PS1 and PS2 integrins[5]. Flies homozygous for null mutations of *mys* die as embryos (see refs 16 and 17 for descriptions of the *mys* lethal phenotype), so to examine the role of integrins in wing morphogenesis, we made clones of cells homozygous for a null mutation of *mys*, along with the flanking markers *yellow* (*y*) and

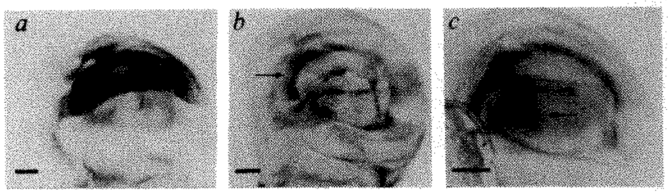

FIG. 1 Anti-PS2-antibody immunofluorescence of the basal surfaces of late third-instar wing imaginal discs. At this stage, the disc consists primarily of a single layered but highly folded columnar epithelium of ~50,000 cells[22]. All micrographs are centred on the 'pouch' region, which evaginates into a flat sac before secreting the cuticle of the adult wing blade[9]. Images are reverse-contrast, so staining is dark. *a*, Wild type. PS2 integrin is found at high concentration throughout the ventral (upper) region of the wing pouch. The sharp horizontal boundary of staining across the pouch marks the line along which the epithelium will fold during evagination (that is, the presumptive wing margin). *b*, Mutant for if^3. PS2 expression is greatly reduced in the pouch. Relatively high levels of staining remain in more peripheral areas, especially along the anterior edge of the pouch (arrow). *c*, Mutant for if^3. Higher magnification of another disc with a less extreme phenotype, showing residual PS2 in the pouch. Typically, expression is greater in the anterior (left) half of the pouch, and is often seen dorsally (arrow) as well as ventrally. Scale bar, 50 μm.

METHODS. Mutants for if^3 were grown as a homozygous stock at 25 °C. Immunofluorescence of wing discs was performed with an anti-PS2 (CF.2C7) monoclonal antibody and fluorescein-conjugated goat anti-mouse antibody (Antibodies Inc.) as previously described[1]. Images were detected with an ISIT video camera, and stored on video tape.

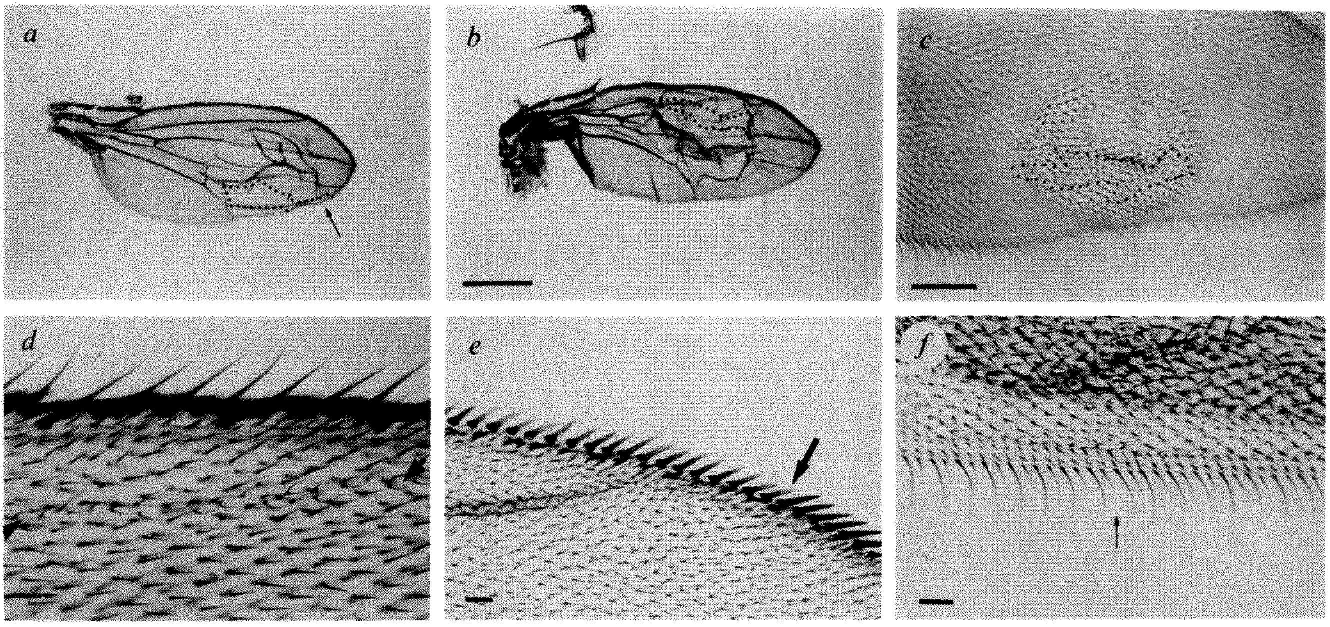

FIG. 3 Homozygous mys^{XG43} clones in adult wings. All clones illustrated were generated by irradiation at 48 ± 4 h after egg laying, except for that shown in *c*, which was generated at 72 ± 4 h. *a*, *b*, Blisters caused by large dorsal (*a*) or ventral (*b*) clones. The approximate extent of the clones is indicated by the dotted outlines; the clone in (*a*) abuts the wing margin distally (arrow). Note that the blisters are much larger than the clones, and are roughly circular. *c*, Blister resulting from small clone. The smooth oval shape of the blister contrasts with the irregular shape of the clone (dotted line). *d*, Long thin clone, which results in a discrete fold in the wing (between arrows), in contrast to the blisters. *e*, Clone along the anterior margin. The arrow indicates the last *y f* marginal bristle of the clone; the darker bristles to the right are wild type. This clone includes 35 bristles of the central row, yet has no obvious effect on the morphology of the margin. Overall, the only margin phenotype that was sometimes observed was that of folding near the wing edge, but this seemed to correlate with the presence of nearby blisters, and was probably an artefact of the more general disruption. *f*, Part of a large dorsal clone that abuts the posterior margin. Long ventrally derived wild-type marginal hairs alternate with shorter dorsally derived *y f* hairs (arrow). This clone includes 69 marginal hairs, all dorsal, in addition to its causing a large wing blister. Scale bars: *a* and *b*, 500 μm; *c*, 100 μm; *d*–*f*, 10 μm.

METHODS. For clonal analysis, *y* $mys^{XG43}f^{36a}/FM7$ females were crossed to wild-type males. The progeny were grown in uncrowded, well-yeasted vials, and irradiated with X-rays (1,500 rads) at 48 or 72 ± 4 h after egg laying, all at 25 °C. As a control, the same cross was performed with the markers but without the mys^{XG43} allele. Embryos homozygous for the mys^{XG43} allele[25] make no immunologically detectable β-subunit (ref. 5, and R. Salatino, unpublished results), and mys^{XG43} behaves as a typical strong allele in various complementation tests (R. Salatino and D.B., unpublished results); we therefore infer that it is a null allele of *mys*. On the basis of sizes and frequencies of mys^{XG43} and control clones, there was no indication that mys^{XG43} reduced cell proliferation. Initially, 133 wings were scored for marked clones without regard to overall wing morphology. These wings yielded 44 mys^{XG43} clones of greater than 50 cells, and virtually all of these clones were associated with clear morphological defects. Subsequently, we examined additional wings selected on the basis of abnormal morphology. Ultimately, a total of 135 wing clones were scored, about half of which included more than 100 cells. Although all results reported here are for the mys^{XG43} allele, similar wing blisters have been observed in clones of another putative null allele, mys^{XB87} (our unpublished observation).

derived central row of the anterior margin, but which did not cross to the other wing surface. These clones apparently reached the presumptive margin after the lineage restriction was established; even so, clones that define the margin over such distances would not be expected if the integrins are important for the maintenance of the lineage restriction.

Although most third instar imaginal disc cells express some surface PS integrin, these proteins are found in particularly high concentrations on the basal surface of the wing pouch epithelium[14]. Also, the spatial specificity of the PS1 and PS2 integrins in this disc region indicates that they are likely to be involved in a specific morphogenetic process there, and we have shown that the integrins are indeed critically important for the proper joining of the dorsal and ventral wing epithelia. It is interesting that our *mys* clones in the leg (15–30 bristles) or abdomen (7–10 bristles) displayed no obvious morphological phenotype (unpublished; see also ref. 21). It seems that the integrins serve a general function in discs, perhaps related to epithelium-matrix connections, but that they additionally perform a much more specialized morphogenetic function in the developing wing. ☐

Requirement of the *Drosophila raf* homologue for *torso* function

Linda Ambrosio*, Anthony P. Mahowald† & Norbert Perrimon*

In *Drosophila* the correct formation of the most anterior and posterior regions of the larva, acron and telson is dependent on the maternally expressed terminal class of genes[1]. In their absence, the anterior head skeleton is truncated and all the structures posterior to the abdominal segment seven are not formed[1–6]. The protein predicted to be encoded by one of these genes, *torso* (*tor*), seems to be a transmembrane protein with an extracytoplasmic domain acting as a receptor and a cytoplasmic domain containing tyrosine kinase activity[7]. Here we report that another member of the terminal-genes class, *l*(1)*polehole* (*l*(1)*ph*)[2,3,8], which is also zygotically expressed, is the *Drosophila* homologue of the v-*raf* oncogene and encodes a potential serine-and-threonine kinase. We also show that functional *l*(1)*ph* gene product is required for the expression of a gain-of-function *tor* mutant phenotype, indicating that *l*(1)*ph* acts downstream of *tor*. Together, these results support the idea that the induction of terminal development occurs through a signal transduction system, involving the local activation of the *tor*-encoded tyrosine kinase at the anterior and posterior egg poles, resulting in the phosphorylation of the *l*(1)*ph* gene product. In turn, downstream target proteins may be phosphorylated, ultimately leading to the regionalized expression of zygotic target genes. Such a process is in agreement with the finding that both *tor* and *l*(1)*ph* messenger RNAs are evenly distributed.

It has been shown previously that the gene encoding a potential serine-and-threonine kinase with homology to the v-*raf* oncogene[9–11] maps near the *l*(1)*ph* locus[12,13]. Molecular analysis of the DNA lesions associated with *l*(1)*ph* mutations indicates that the *Drosophila raf* homologue, *D-raf*, is in fact the *l*(1)*ph* gene (Fig. 1). Confirmation of the identity of *D-raf* and *l*(1)*ph* was obtained by P-element-mediated rescue experiments. A DNA fragment of 4.3 kilobases (kb) containing only the *D-raf* coding sequences rescued both the zygotic and maternal effects of *l*(1)*ph* mutations (Fig. 1*b*).

The *D-raf* transcripts are distributed homogeneously

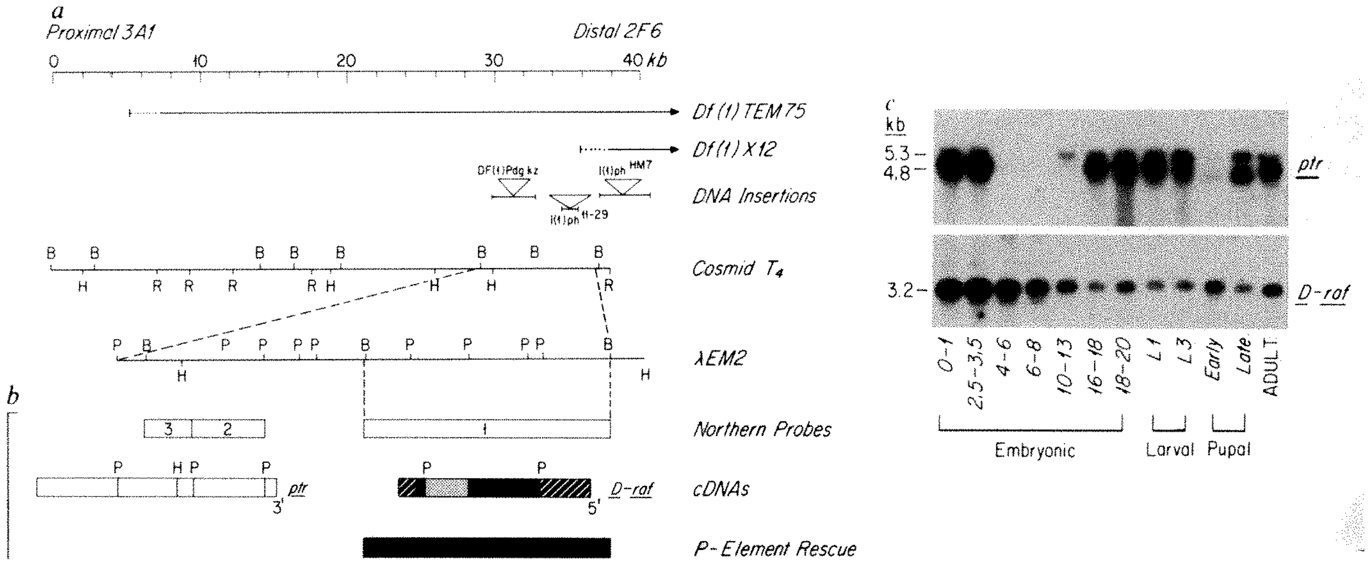

FIG. 1 The molecular organization of the 2F6-3A1 cytogenetic region containing the *l*(1)*ph* locus. The reference bar is graduated in kb with the position 0 defined by the proximal end of the T4 cosmid[23]. *a*, The *l*(1)*ph* gene lies between deficiency breakpoints *Df(1)TEM75* and *Df(1)X12*[8] which map to positions 6–8 and 36–38, respectively. The solid lines represent DNA sequences not removed by the deficiencies and the broken lines represent the maximum limits within which the deficiency breakpoints fall. *Df(1)TEM75* complements *l*(1)*ph* mutations, defining a proximal limit for the *l*(1)*ph* gene. The *Df(1)X12* chromosome does not complement *l*(1)*ph* mutations, indicating at least some of the *l*(1)*ph* gene lies proximal to the breakpoint at position 36–38. DNA polymorphisms in three different strains are identified as insertions in the *l*(1)*ph* region. Two mutant alleles of *l*(1)*ph*, $l(1)ph^{HM7}$ and $l(1)ph^{11-29}$ (L.A., manuscript in preparation) have ~4-kb DNA insertions mapping to positions 38–41 and 35–36, respectively. The *Df*(1)*Pdg kz* chromosome has wild-type *l*(1)*ph* activity but contains a 7-kb DNA insertion at position 30–33. These DNA insertions are depicted at their approximate positions by the inverted triangles. The deficiency breakpoints and DNA insertions were mapped using standard methods as described previously[24]. *b*, Two non-overlapping transcription units lie within the genomic region containing the *l*(1)*ph* gene. The *D-raf* gene was localized to position 33–37 using a *Bam*H1 subclone (nothern-blot probe 1) of the genomic probe *D-raf1* (ref. 12). A second transcription unit called *ptr* (proximal to *raf*) was identified by northern-blot analysis using probes 2 and 3. No additional bona fide transcription units are encoded within the DNA spanning positions 0–40. Complementary DNAs homologous to *D-raf* and *ptr* transcription units were isolated from λgt11 (gift of K. Zinn and C. Goodman) and plasmid pNB50 (ref. 25) cDNA libraries, respectively. The 3.2-kb *D-raf* cDNA contains both 700 base pairs-5′ and 600 base pairs-3′ nontranslated regions (hatched boxes), and a coding region of 1.9 kb (shaded boxes) which includes the putative serine-threonine kinase domain (vertical striped box). The 4-kb insertion in $l(1)ph^{11-29}$ maps within the *D-raf* coding region, whereas the $l(1)ph^{HM7}$ insertion maps 5′ to it. The complete structure of the 4.3 kb *ptr* cDNA has not been determined; but the *Df*(1)*Pdg kz* DNA insertion occurs within sequences encoding the *ptr* transcript. *Df*(1)*Pdg kz*/*Df*(1)*X12* females show only truncated *ptr* transcripts, have the normal 3.2 kb *D-raf* transcript, and are viable, fertile adults (data not shown). These data indicate that it is the *D-raf* rather than the *ptr* transcription unit which encodes the *l*(1)*ph* gene. A transformed strain, B-13-1 (ref. 13) containing a P-element construct carrying the wild-type *D-raf* gene was tested for complementation to *l*(1)*ph* mutations. All pleiotropic aspects of the mutant *l*(1)*ph* phenotype including the maternal effect, were rescued by the transformed DNA fragment *in trans* configuration (data not shown). *c*, Accumulation of *ptr* and *D-raf* transcripts during development. The *ptr* transcription unit encodes a 5.3 kb and a 4.3 kb RNA species and its expression is developmentally regulated. The 3.2 kb *D-raf* transcript is present at all stages of development. The time points for the embryonic period are given as hours after egg laying. These northerns blots re-probed with an actin 5C probe indicate that each lane contains an equivalent concentration of RNA (data not shown). Preparation of poly(A)$^+$ RNA and northern-blot analysis were performed as described previously[26].

throughout the oocyte and embryo at all stages (Fig. 2) and are not preferentially localized to the termini. Based on evidence presented below, it is likely that the maternal *D-raf*-encoded protein is also evenly distributed in the embryo. Similarly, there is no specific pattern to the localization of *tor* mRNA in the egg or embryo, and a uniform distribution of *tor* gene product is also predicted[7]. Thus the spatial restriction of both *D-raf* and *tor* activities, and hence the proper determination of terminal cell fates, does not rely on the spatial localization of the corresponding gene products, but could rather depend on their localized activation, possibly by one of the other terminal genes.

The finding that the proteins encoded by *D-raf* and *tor* contain domains with potential kinase activities indicates a possible mechanism by which such restricted activity of evenly distributed gene products occurs. In mammalian cells, the proto-oncogene homologue of v-*raf*, *c-raf-1* (refs 14, 15) encodes a protein which functions as a transducer of extracellular growth signals. Binding of growth factors, such as epidermal growth factor (EGF) and platelet-derived growth factor (PDGF) to receptors with tyrosine kinase activity causes the phosphorylation of *c-raf-1* product and the stimulation of its kinase activity[16]. Activated *c-raf-1* protein in turn phosphorylates other proteins, which may include itself and transcription factors, to initiate the programme for cell division. The proteins encoded by *tor* and *D-raf* could function in an analogous signal transduction pathway. The *tor* gene product could be the receptor for a spatially localized 'terminal' signal potentially secreted by the follicle cells during oogenesis. Binding of the localized ligand to the extracellular receptor domain of the *tor* gene product would activate the kinase domain, which would then locally phosphorylate the ubiquitous *D-raf* gene product. Thus, local activation of the *D-raf* gene product would lead to the induction of a programme of zygotic gene expression specific for the termini of the embryo.

We tested genetically for the interactions between *tor* and *D-raf* which such a model predicts. Loss-of-function alleles of *tor* lead to the loss of terminal structures identical to those described for null *l*(1)*ph* mutations. The maternal effect of some *tor* alleles, however, produce an opposite, gain-of-function embryonic phenotype[17,18]. Females homozygous for the *tor* gain-of function allele tor^{RL3} produce at 25 °C embryos that lack thoracic and abdominal structures but show differentiation of the terminal anlagen. Loss of abdominal segments is correlated with the suppression of early gap and segmentation gene expression, indicating that tor^{RL3} could encode a protein which is ectopically active in the central domain of tor^{RL3}-derived embryos[17,18].

If the *D-raf* gene product is required to transfer the activated *tor* signal to other downstream terminal genes, then the absence of *D-raf* should suppress the tor^{RL3} gain-of-function phenotype. To test whether this occurs, embryos derived from eggs lacking maternal *D-raf* and containing tor^{RL3} activities were examined. Two classes of embryos were observed with equal frequency after 24 hours of development at either 18 °C or 25 °C. Class 1 embryos showed the terminal class defect, with anterior and posterior regions of the embryos failing to develop. These embryos most probably represent the progeny lacking maternal *D-raf* activity. Class 2 embryos suffered massive cell death and developed little cuticle. These embryos are equivalent to those lacking both maternal and zygotic *D-raf* activity. No embryos exhibited the tor^{RL3} phenotype. Thus, functional *D-raf* gene product is required for expression of the gain-of-function tor^{RL3} phenotype. Loss of *D-raf* gene product blocks the transfer of the *tor* terminal signal in the central domain and at the termini of tor^{RL3}-derived embryos. This result also indicates that *D-raf* gene product is present and can be activated in the central domain of tor^{RL3} and wild-type embryos, which is consistent with the ubiquitous presence of *D-raf* transcripts (Fig. 2).

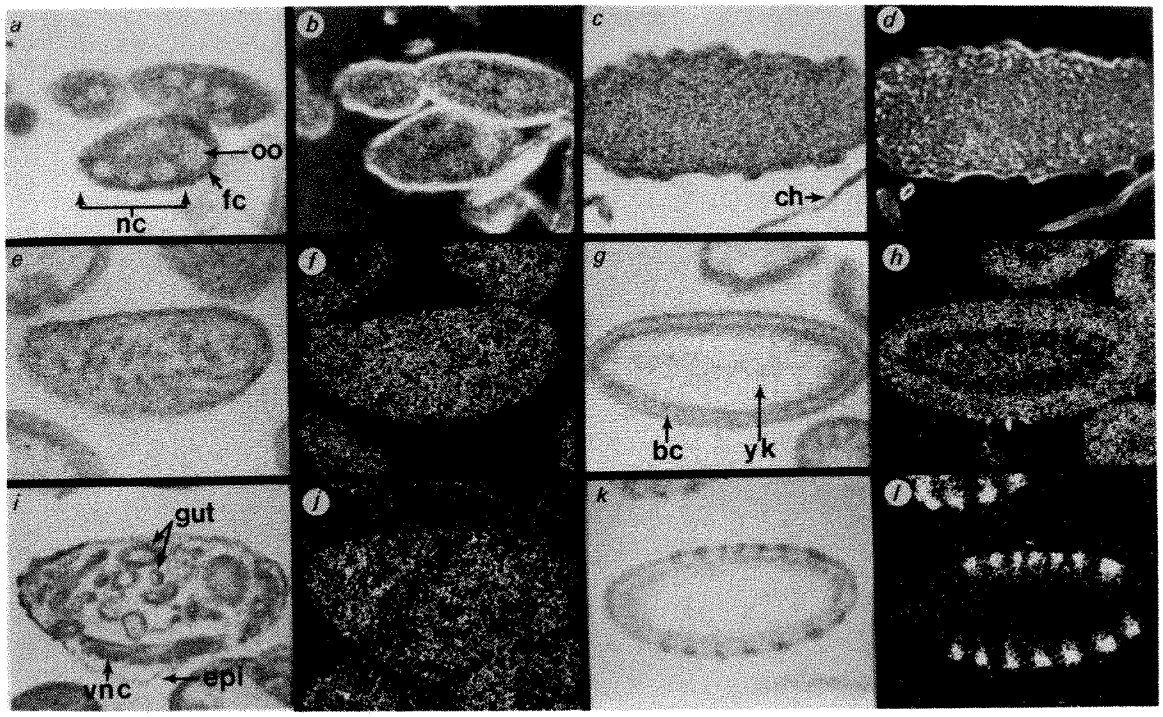

FIG. 2 Accumulation of *D-raf* transcripts during oogenesis and embryogenesis. *a, b*, An equal distribution of *D-raf* transcripts is observed for germ-line-derived nurse cells, oocyte and somatic follicle cells at stages 5–9 of oogenesis. *c, d*, A mature stage-14 oocyte shows no spatial localization of maternal *D-raf* RNAs. *e, f*, Accumulation of *D-raf* RNA in a syncitial blasoderm staged embryo 2 h after fertilization. *g, h*, At 3 h, *D-raf* RNA is present in the peripheral blastoderm cells and in the internal yolk region. *i, j*, At later stages of embryogenesis (16 h) *D-raf* transcripts are present in endodermal, mesodermal and ectodermal tissues. *k, l*, Control blastoderm stage embryo showing localization of *fushi tarazu* (*ftz*) transcripts[27]. Preparation of tissue sections and hybridization conditions using ^{35}S-labelled *D-raf* and *ftz* probes were as described previously[26]. Abbreviations: bc, blastoderm cells; ch, chorion; epi, epidermis; fc, follicle cells; nc, nurse cell complex; oo, oocyte; vnc, ventral nerve cord; yk, yolk.

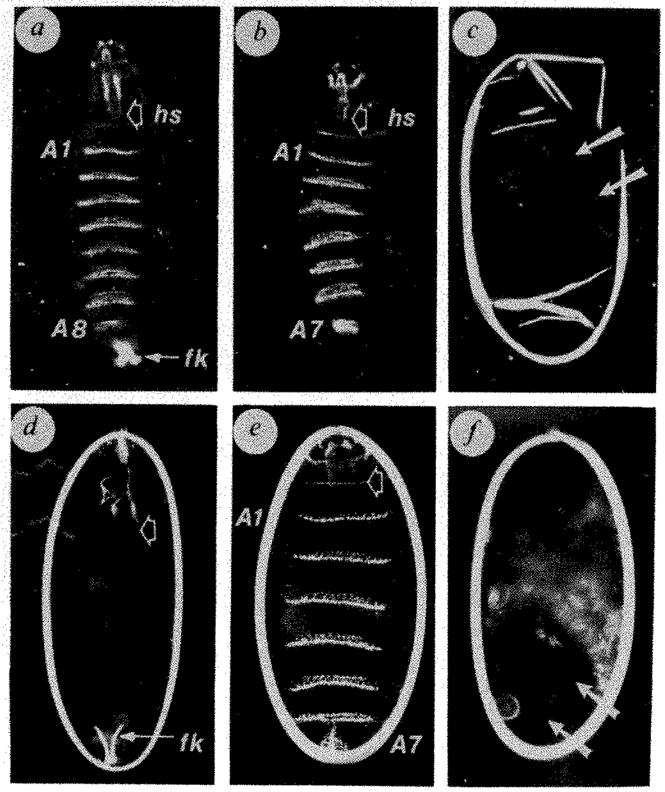

FIG. 3 The phenotype of embryos derived from double mutant *l*(1)*ph* and tor^{RL3} female germ cells. Dark field photographs of cuticular preparations of wild-type embryos (*a*) and of embryos derived from: homozygous *l*(1)*ph* female germ cells (*b*, *c*); homozygous tor^{RL3} females (*d*); homozygous *l*(1)*ph*;tor^{RL3} female germ cells (*e*, *f*). In *b* and *e*, embryos show the terminal class phenotype: a truncated head skeleton and the lack of structures posterior to abdominal segment seven. These embryos developed without maternal *D-raf* activity. In *c* and *f*, embryos show the *l*(1)*ph* 'null' phenotype; little cuticle is formed. These embryos developed without maternal and zygotic *D-raf* activity. *d*, The tor^{RL3} gain-of-function phenotye: at 19 °C embryos form head and tail structures without thoracic or abdominal segments. The $l(1)ph^{EA75}$ allele used to generate female germ cells lacking *D-raf* activity as previously described[28]. All females were crossed to Oregon R wild-type males. Abbreviations: fk, filzkorper; hs, head skeleton.

TABLE 1 Partial suppression of the tor^{RL3}

Maternal genotype	*T* (°C)	*N*	No. of embryos hatched	Hatching (%)
A. tor^{RL3}/tor^{RL3}	18	1,920	20	1
	19	2,812	0	0
	20	1,882	0	0
B. *l*(1)*ph*/*FM3* tor^{RL3}/tor^{RL3}	18	1,906	220	11.5
	19	2,788	110	3.9
	20	1,320	3	0.22
C. ±/*FM3*: tor^{RL3}/tor^{RL3}	18	1,950	30	1.5
	19	1,478	11	0.7
	20	1,520	0	0

The frequency of embryonic hatching was assayed 48 h after egg laying; females were mated to Oregon R wild-type males. *A*, Eggs produced by tor^{RL3}/tor^{RL3} females collected from the original stock obtained from T. Schupbach. For *B* and *C* the following stock was made: $l(1)ph/FM3/Dp(1;Y)w^{+303};tor^{RL3}/CyO$. From this stock *l*(1)*ph*/*FM3*; tor^{RL3}/tor^{RL3} females were collected and assayed in *B*. For the females assayed in *C*, *l*(1)*ph*/*FM3*; tor^{RL3}/CyO females were mated to tor^{RL3}/CyO males and the ±/*FM3*; tor^{RL3}/tor^{RL3} females collected. In this experiment, surviving larvae were phenotypically normal and some developed into adults. The unhatched embryos had segmentation defects which were more extreme at 20 °C than at 18 °C. A null allele, $l(1)ph^{EA75}$, was used in this study. Descriptions of balancer chromosomes, *FM3* and *CyO* in ref. 22.

Suppression of the gain-of-function tor^{RL3} phenotype is also observed in embryos derived from eggs containing only half the wild-type amount of *D-raf* gene product. At 18 °C, the proportion of embryos that hatched was greater for these embryos than for those with normal levels of *D-raf* activity (Table 1). The maternal effect of tor^{RL3} is cold sensitive[18]; at 25 °C, embryos show complete loss of abdominal segmentation, whereas at 18 °C a few embryos (1%) have normal segmentation and hatch. This weak gain-of-function phenotype of the tor^{RL3} allele at 18 °C is indicative of a low-level of ectopic *tor* activity. But when the maternal contribution of functional *D-raf* gene product was reduced by half there was a 10-fold increase (11%) in the number of embryos that survive to hatching. The enhanced survival can be attributed to the reduced levels of maternal *D-raf* activity, and, thus, to an indirect reduction of ectopic tor^{RL3} activity. When the availability of *D-raf* gene product is reduced, the efficiency of signal transfer may also decrease, thereby restoring normal embryonic development. At the termini, where the activity of tor^{RL3} is at least normal, a 50% reduction of *D-raf* product does not adversely affect the development of head or tail structures.

These results support the idea that induction of terminal development acts through a signal transduction system involving a phosphorylation cascade. Spatial restriction of activity is achieved in this pathway by the localized activation of evenly distributed gene products. Two genes likely to participate in this cascade are *tor* and *l*(1)*ph* (*D-raf*). We have shown here that *D-raf* acts downstream of the *tor* gene product to transfer the maternal terminal signal. Our data is consistent with the model proposed above and by Sprenger *et al.*[7]: activation of *tor*-encoded tyrosine kinase in a spatially restricted manner results in the phosphorylation of *D-raf* gene product, which in turn phosphorylates serines and threonines of downstream target proteins. One such target could be the protein encoded by the *tailless* (*tll*) gene[19]; phosphorylation by *D-raf* gene product of maternally expressed Tll protein[18] could cause its activation, leading directly or indirectly to zygotic expression of *tll*. Other downstream terminal genes, including *fork head*[20] and *spalt*[21] could play a part in mediating the terminal class signal transmitted by *D-raf*.

In contrast to the other maternal terminal class genes, *l*(1)*ph* gene activity is also required at later embryonic and larval stages of development for the maintenance of cell viability[3] and for the proliferation of somatic cells[2], respectively. Thus the *l*(1)*ph* gene product acts in several different developmental pathways; only its maternal role in the terminal class pathway has been addressed here. ☐

Perkins for the northern blot, and D. Smouse for discussion and comments on the manuscript. This work was supported by grants from the Howard Hughes Medical Institute and the NIH.

Substantial increase of protein stability by multiple disulphide bonds

Masazumi Matsumura*, Giovanni Signor & Brian W. Matthews

Institute of Molecular Biology and Department of Physics,
University of Oregon, Eugene, Oregon 97403, USA

DISULPHIDE bonds can significantly stabilize the native structures of proteins[1–3]. The effect is presumed to be due mainly to a decrease in the configurational chain entropy of the unfolded polypeptide[4–7]. In phage T4 lysozyme, a disulphide-free enzyme, engineered disulphide mutants that crosslink residues 3–97, 9–164 and 21–142 are significantly more stable than the wild-type protein[8–11]. To investigate the effect of multiple-disulphide bonds on protein stability, mutants were constructed in which two or three stabilizing disulphide bridges were combined in the same protein. Reversible thermal denaturation shows that the increase in melting temperature resulting from the individual disulphide bonds is approximately additive. The triple-disulphide variant unfolds at a temperature 23.4 °C higher than wild-type lysozyme. The results demonstrate that a combination of disulphide bonds, each of which contributes to stability, can achieve substantial overall improvement in the stability of a protein.

Unpaired cysteine residue(s) in a protein containing a disulphide bond(s) can lead to oligomerization through thiol/disulphide interchange[12]. Previously described single-disulphide mutants (designated as 3C–54T, 9C–164C-wt* and 21C–142C-wt*, see Fig. 1) were, therefore, constructed in an otherwise cysteine-free pseudo wild-type lysozyme (wt*)[11,13]. For the same reason the two double-disulphide mutants D3–97/9–164 and D9–164/21–142 and the triple disulphide mutant T3–97/9–164/21–142 were also designed and constructed to have no unpaired cysteines. Figure 1 shows the locations of the disulphide bonds and ancillary mutations introduced into T4 lysozyme. Each of the mutant genes was expressed in *Escherichia coli* and the proteins purified to homogeneity. Immediately after purification, the mutant enzymes were found to be a mixture of oxidized (crosslinked) and reduced (noncrosslinked) forms, as judged by ion-exchange high-performance liquid chromatography (HPLC)[11], reversed-phase HPLC[8,13] and titration of protein thiols with Ellman's reagent (data not shown). After exposure of proteins to air under mild alkaline conditions (pH 8.0) for several days, however, the mutant proteins were all converted to the oxidized forms (Table 1). Nonreducing SDS-PAGE showed that the double- and triple-disulphide mutants migrate faster than the disulphide-free wild-type lysozyme, whereas all the multiple-disulphide mutants had mobility identical with wild type in the presence of reducing agent (data not shown). This observation indicates that the crosslinked proteins have a more compact structure in the denatured state.

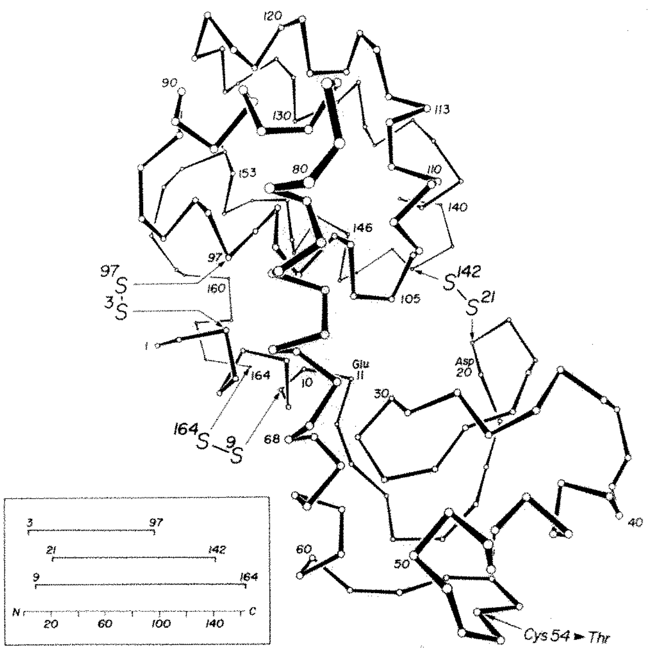

FIG. 1 Backbone of T4 lysozyme showing the locations of the three engineered disulphide bridges. The insert illustrates the loops formed by these bridges. Identification and generation of the mutant lysozymes is as follows:

Variant	Amino-acid replacements 3	9	21	54	97	142	164	No. of cysteines	No. of disulphide bonds
wt	Ile	Ile	Thr	Cys	Cys	Thr	Leu	2	0
wt*				Thr	Ala			0	0
3C–54T	Cys			Thr				2	1
9C–164C-wt*		Cys		Thr	Ala		Cys	2	1
21C–142C-wt*			Cys	Thr	Ala	Cys		2	1
D3–97/9–164	Cys	Cys		Thr			Cys	4	2
D9–164/21–142		Cys	Cys	Thr	Ala	Cys	Cys	4	2
T3–97/9–164/21–142	Cys	Cys	Cys	Thr		Cys	Cys	6	3

Recombinant DNA techniques used in the construction of the disulphide mutants were essentially as described[17]. Mutagenic oligonucleotides (21–23 mer) were synthesized using a model 380B DNA synthesizer (Applied Biosystems) and purified by a C18 Sep-Pak cartridge (Millipore). The single-stranded DNA template for site-directed mutagenesis was an M13mp18 derivative containing the T4 lysozyme gene on a 630 base-pair *Bam*HI–*Hind*III fragment. The mutagenesis was performed according to Kunkel *et al.*[18] using *E. coli* strain CJ236 (*dut1, ung1, thi1, relA1*/pCJ105 (Cm^r)). After the repair synthesis of DNA *E. coli* JM101 (ref. 19) was transformed and the mutants identified either by DNA sequencing[20] or plaque hybridization with the $[^{32}P]$-labelled mutagenic prime[21]. The mutations were verified by sequencing the entire T4 lysozyme gene. The mutated T4 lysozyme gene on M13 was digested with *Bam*HI and *Hind*III, and cloned into the expression plasmid pHSe5 that contains *tac* and *lac*UV5 promoters, $lacI^q$ gene as well as *trp* terminator[22]. *E. coli* RR1 (ref. 17) was then transformed by the recombinant pHSe5 and the mutant protein was overproduced by addition of isopropyl-β-thiogalactoside. The mutant proteins were purified to homogeneity by CM-Sepharose and SP-Sephadex (Pharmacia) chromatography as described[22].

The activity of the D3–97/9–164 mutant (Table 1) is indistinguishable from that of wild-type enzyme in both the oxidized and reduced forms. The result is consistent with the observation that the corresponding single-disulphide mutants have essentially the same activities as wt* in both oxidized and reduced forms[11]. In addition it indicates that virtually all the D3–97/9–164 molecules have the correct pairing of the disulphide bridges as any mispairing would presumably lead to a loss of activity. The wt* lysozyme loses enzymatic activity at ~55 °C at pH 7.4, whereas the D3–97/9–164 mutant, which is more thermostable than wt* by 15.7 °C at pH 2.0 (see below), retains activity up to

	Red	4.1	100	31.6	−10.3	
D9-164/21-142	Ox	0.0	0	58.9	17.0	22.9
	Red	4.1	58	36.0	−5.9	
T3-97/9-164/21-142	Ox	0.2	0	65.5	23.4	31.9
	Red	6.0	43	33.4	−8.5	

Oxidized (crosslinked) mutant lysozymes were prepared on exposure to air *in vitro* by incubating in 0.1 M Tris-HCl, 0.15 M NaCl (pH 8.0) for several days. The reduced (noncrosslinked) forms of the mutant lysozymes were prepared by treating the purified proteins (~1 mg ml^{-1}) with 6 M guanidine hydrochloride, 20 mM DTT and 1 mM EDTA in 50 mM Tris-HCl (pH 8.3). After incubation for 4 h at 23 °C, the mixture was extensively dialysed under a nitrogen gas purge at 4 °C against 0.2 M NaCl and 1 mM EDTA (pH 2.0). Under the nitrogen atmosphere and at acid pH, the reduced proteins were stable for at least a week at 4 °C. Thiol content was determined by Ellman titration[23]. A 0.5 ml fraction of the oxidized or reduced protein (0.02 μmole) was mixed with 2.5 ml of a solution containing 2% SDS, 0.08 M sodium phosphate (pH 8.0), and 0.5 mg ml^{-1} EDTA. To 3 ml of the solution was immediately added 0.1 ml 5,5-dithiobis (2-nitrobenzoic acid) (DTNB) (40 mg DTNB in 10 ml of 0.1 M sodium phosphate, pH 8.0). After 15 min, the absorbance at 410 nm was measured. Lysozyme activities were measured at 23 °C using the turbidity assay[24]. Protein concentrations were determined spectrophotometrically (molar absorption coefficient for wild-type T4 lysozyme $\epsilon^{0.1\%}_{280\,\mathrm{nm}}=1.28$) (ref. 24). T_m is the temperature at the midpoint of the thermal denaturation transition at pH 2.0. ΔT_m(mut-wt*) and ΔT_m(ox-red) are the differences between mutant and wt* lysozyme and between the oxidized and reduced mutant protein, respectively. Data for wild type and single S-S bridge lysozymes are from refs 10, 11 and 25. Thermal stability was assessed at pH 2.0 by measuring the circular dichroism at 223 nm as a function of temperature[26,27]. Solutions contained ~0.02 mg ml^{-1} protein, 0.15 M KCl and 1 mM EDTA, adjusted to pH 2.0 with HCl. To avoid air oxidation, the experiments were performed in a nitrogen atmosphere and the KCl-EDTA solutions were extensively bubbled with nitrogen gas before use[28].

~65 °C (data not shown). Mutants D9-164/21-142 and T3-97/9-164/21-142, which include the 21-142 disulphide bond, have virtually no catalytic activity in the oxidized form. This is expected as the 21-142 disulphide bond spans the 'mouth' of the active-site cleft (Fig. 1) leading to the complete abolition of lysozyme activity[13].

The melting temperatures of the single and multiple disulphide bridge mutants at pH 2.0 are summarized in Table 1 and Fig. 2. Both the double mutants are more heat-stable than their constitutent single mutants. In the case of the triple mutant the increase in melting temperature (ΔT_m) is substantial (23.4 °C) and agrees surprisingly well with the sum of the ΔT_ms of the corresponding single disulphide variants (22.2 °C). Measurement of the melting temperature at higher pH values is difficult because the solutions approach boiling point before the unfolding transition is complete. As a guide, however, the estimated reversible melting temperature of the triple disulphide mutant at pH 5.0 is 86 °C, which is 20 °C higher than wild type at the same pH.

It is presumed that a consequence of a disulphide bridge is to reduce the configurational backbone chain entropy of the protein in the denatured state, thus increasing the stability of the folded protein[3-7]. Theoretical considerations suggest that the entropic contribution to the free energy of stabilization increases in proportion to the logarithm of the number of residues in the loop formed by the disulphide bridge[3-6]. When multiple, overlapping disulphide bonds are introduced into a protein, their effects on the configuration of the unfolded protein are interdependent, and the determination of the entropic term becomes more complicated[6,7,14]. Nevertheless, reasonable agreement between experiment and theory has been observed for ribonuclease A[6,14], ribonuclease T1 (ref. 3) and hen egg-white lysozyme[15]. Based on theory,[14] the reductions in entropy in the unfolded protein caused by the single 3-97, 9-164 and 21-142 bridges are, respectively, 20.5, 21.9 and 21.2 entropy units. The sum of these three terms, considered independently, is 63.6 entropy units, which corresponds to 20.0 kcal mol^{-1} at 42 °C, the melting temperature of wild-type lysozyme at pH 2.0. By contrast, the theoretically estimated[14] entropy reduction when all three bridges are included in the same protein is 56.7 entropy units, corresponding to 17.9 kcal mol^{-1}. Thus, even though the loops formed by the three disulphide bridges have substantial overlap (Fig. 1), this has only a relatively small effect on the

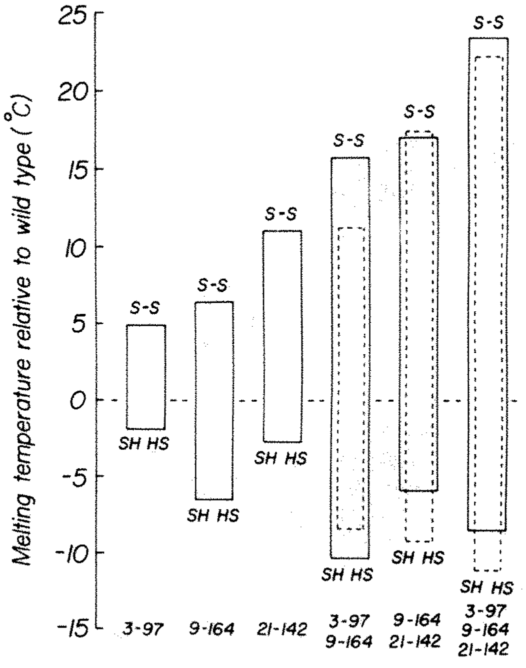

FIG. 2 Melting temperatures of single, double and triple-disulphide bonded lysozymes relative to wild-type lysozyme (ΔT_m) at pH 2.0. The solid bars show the observed melting temperatures of the oxidized and reduced forms of the mutant lysozymes (Table 1). The broken bars for the multiply bridged proteins correspond to the sums of the ΔT_ms for the constitutent singly bridged lysozymes.

overall entropy term. Although each disulphide bridge reduces the conformational freedom of the unfolded chain, this restriction represents only a small fraction of the total number of conformational states that are available. Thus, the contributions to stability from each of the three disulphide bridges are still largely additive. The crosslinked lysozymes display a correlation between the number of disulphide bonds and the Stokes radii of the denatured proteins, as judged by gel filtration HPLC in the presence of urea[16]. This also indicates that the crosslinks successively decrease the configurational freedom of the unfolded protein.

The above arguments are based on entropy considerations alone. As discussed in ref. 11, the net stabilization of a given disulphide bond depends on other factors, such as the loss of stabilizing interactions associated with introduction of the cysteine(s) and possible introduction of strain associated with the closure of the disulphide bridge. In the case of T4 lysozyme, factors that seem to be helpful in the design of the stabilizing disulphide bridges include the use of large loops to maximize the entropic effect on the unfolded state and the choice of flexible sites to avoid the introduction of strain into the folded protein[11]. Exploration of the energetic and theoretical basis of the observed stabilization of the multiply bridged lysozymes will require detailed thermodynamic analysis of these proteins.

In terms of the goal of developing general methods to increase the stability of proteins, the present results are especially encouraging. They demonstrate that individual S–S bridges can be combined together to dramatically enhance stability, even in cases where the disulphide bridges form overlapping loops. It is also encouraging to find that the double-disulphide mutant D3-97/9-164 is fully active and also retains activity at temperatures substantially higher than wild-type lysozyme. This shows that a protein does not have to be marginally stable in order to be fully active. Instead, the present results indicate that the stability of a protein can be substantially increased with no loss in enzymatic activity. □

ALTHOUGH the dynamic behaviour of chromosomes has been extensively studied in their condensed state during mitosis, chromosome behaviour during the transition to and from interphase has not been well documented. Previous electron microscopic studies suggest that chromosomes condense in a non-uniform fashion at the nuclear periphery[1,2]. But chromosome condensation is a complicated and dynamic process and requires continuous observation in living tissues to be fully understood. Using a recently developed three-dimensional time-lapse fluorescence microscopy technique[3], we have observed chromosomes as they relax from telophase, through interphase, until their condensation at the next prophase. This technique has been improved to produce higher-resolution images by implementing new stereographic projection and computational processing protocols[4]. These studies have revealed that chromosomal regions on the nuclear envelope, distinct from the centromeres and telomeres, serve as foci for the decondensation and condensation of diploid chromosomes. The relative positions of the late decondensation sites at the beginning of interphase appear to correspond to the early condensation sites at the subsequent prophase.

In order to study the chromosomal events that occur between telophase and the ensuing prophase, we have followed embryonic nuclei of *Drosophila melanogaster* during the late syncytial blastoderm period. Chromosomes in living *Drosophila* embryos were visualized by imaging chromatin which had assembled fluorescent-labelled histones into nucleosomes. Calf thymus histones H2A and H2B were conjugated with rhodamine and microinjected into *Drosophila* embryos 30 minutes after oviposition to ensure a uniform distribution of the labelled histones by the time of observation. The injected rhodamine-labelled histones are stably incorporated into chromatin during periods of DNA replication. Under low levels of illumination, these embryos can be observed for more than three hours and develop normally to hatching.

Observing the behaviour of an entire nucleus requires a three-dimensional analysis over time. Imaging at low light levels was accomplished using a cooled, scientific grade charge-coupled device (CCD) imager[5,6] operated by a self-contained computer workstation. Three-dimensional data sets were obtained by digitally recording a series of five optical sections taken at 1 μm focal intervals every five seconds, as described in the legend to Fig. 1. By repeating this optical sectioning protocol every 25 seconds, a time-lapse series of 80 three-dimensional data sets was recorded. The period of analysis spanned nuclear cycles 12 and 13 of syncytial blastoderm stage embryos. During this stage of embryonic development, the nuclei form an almost synchronously replicating monolayer on the embryo surface[7,8]. The nuclear cycle length for the embryo shown in Fig. 1 was 22 minutes at 23 °C. Embryos were monitored after data collection to verify that gastrulation occurred normally.

To facilitate analysis of the large amount of three-dimensional data over time, a time-lapse stereo movie was constructed using the synthetic projection method[4] described in the legend to Fig. 1. Briefly, a stereo pair of projected images is formed from each set of optical section data by sequentially shifting each image either left or right and summing to generate the projections. The projected images are then computationally processed to remove out-of-focus information[4]. For projected images, this is a simple and straightforward process which can provide nearly exact deblurring. Furthermore, as no light is rejected in the image processing, unlike confocal microscopy, this approach is ideal for the low-light level imaging required for *in vivo* analysis. The resultant in-focus stereo projection images were sequentially displayed in rapid succession as a time-lapse movie. Examples of selected frames of the movie are shown as stereo pairs in Fig. 1.

Examination of the real-time, three-dimensional data revealed that chromosome decondensation terminates and condensation initiates at discrete sites predominantly on the nuclear envelope (visualized as bright spots; Fig. 2*a–e*). Chromosomes begin to decondense shortly after chromatid separation, and by the following interphase, nuclei labelled with rhodamine-conjugated histones show an essentially uniform appearance. Surprisingly, examination of the kinetics of chromosome decondensation revealed that a small portion of the chromosomes remained condensed at several sites on the nuclear envelope (2–3 sites per nucleus) after most of the chromosomes had decondensed (about 5 minutes after the metaphase–anaphase transition of the twelfth cycle). The location of these sites can be seen clearly at the nuclear periphery (indicated by arrows in Fig. 2*a–e*, column 1). Because these late decondensation sites eventually disappear to make a uniformly stained nucleus during interphase (about 6 minutes after the metaphase-anaphase transition; see Fig. 1, frame at 6:40 min), they are not consistent with the classical definition of heterochromatin.

At the transition from interphase to prophase, bright spots of chromosome condensation were also observed at discrete sites on the nuclear envelope (indicated by arrows in Fig. 2*a–e*, columns 3-6). The first of these condensation sites appears 10 minutes after nuclear division, with new sites continuing to

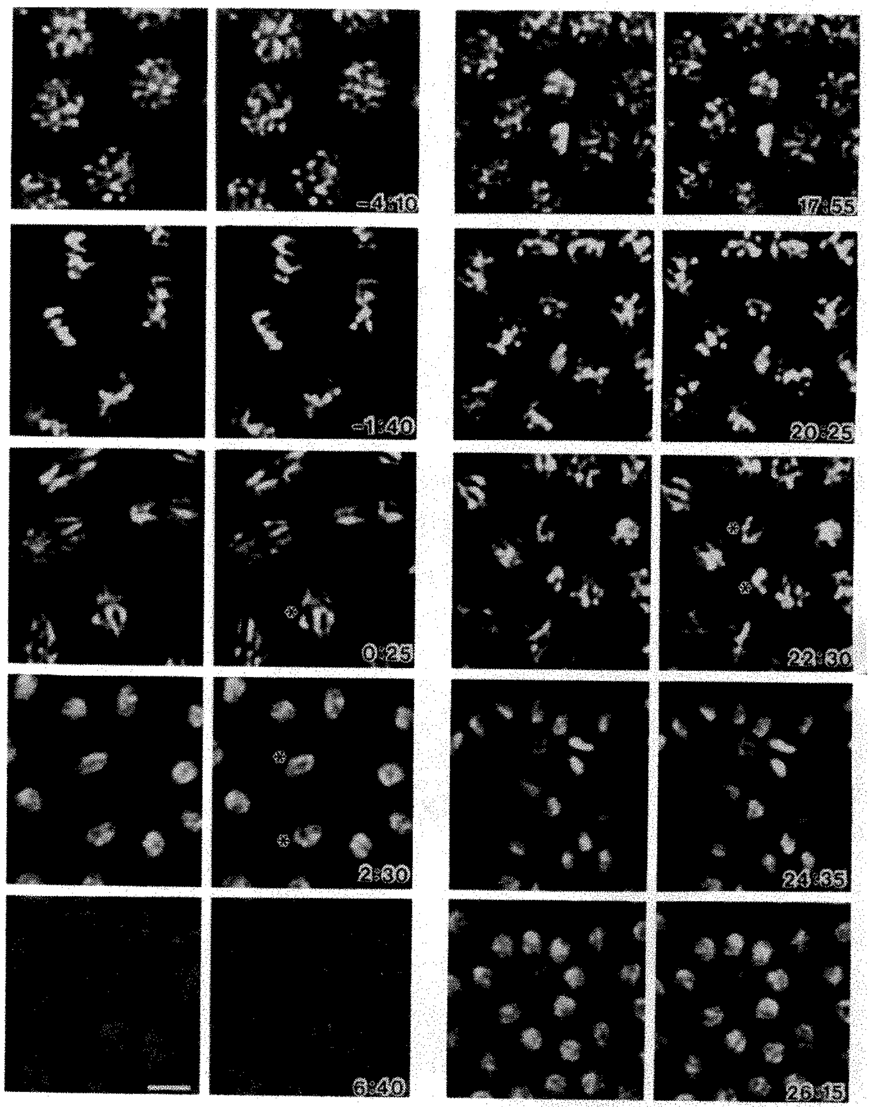

FIG. 1 Stereo pairs selected from the time-lapse data. The numbers represent time in minutes:seconds after the 12th nuclear division. Time is stated relative to the onset of chromosome separation at the metaphase–anaphase transition; a negative sign is given to data dets taken before the 12th nuclear division. Asterisks indicate damaged nuclei (see text and also Fig. 2). Scale bar represents 5 μm.

METHODS. Recording three-dimensional data from living embryos: A standalone, computer workstation CCD system was used which provides real-time capability with a lower digital resolution (12 bits versus 14 bits) but a faster readout rate (200,000 pixel per second versus 50,000 pixel per second) than our previously reported system[5]. All aspects of microscopy, data collection, data storage, image processing and display can be performed on the one workstation. A Peltier-cooled CCD camera (Photometrics, Tucson, Arizona) with a 1340 × 1037 pixel CCD chip (Kodak-Videk) coated to improve short-wavelength response[6], is attached to an IMT-2 Olympus inverted microscope. Microscope shutter, focus movement and CCD data collection are controlled by a MicroVax III workstation coupled to a 20 MFLOPS Mercury Zip 3232 + array processor (Mercury Computer Systems, Lowell, Massachusetts) and a Parallax model 1280 graphic display system having 12 Mbyte of image memory (Parallax Graphics, Santa Clara, California). Calf thymus histones were bound to double-strand DNA cellulose to form nucleosomes, labelled with 5(6)-carboxytetramethyl rhodamine *N*-hydroxysuccinimidyl ester (Molecular Probes, Eugene, Oregon), and eluted with a salt gradient. Rhodamine-labelled histones H2A and H2B, at 0.4 mg ml^{-1}, were microinjected into *D. melanogaster* embryos. Details of the method are reported elsewhere[3]. The rhodamine-histone injected embryos were illuminated with a 100W mercury arc lamp attenuated 20-fold by a neutral density filter and observed using an Olympus 40×/NA1.3 oil immersion objective lens and a high selectivity rhodamine filter combination (Omega Optical, Brattleboro, Vermont). To speed up the image readout, images were taken on a small portion of the CCD, 256 × 256 pixels corresponding to 44 × 44 μm area with a pixel size of 0.17 μm. Five optical section images were recorded at an interval of 1 μm with an exposure time of 0.1 s. It took 5 s to read out correct and store each image; thus, 25 s for one cycle of a focus series. This was repeated 80 times to form a time course. Generation of a time-lapse stereo movie: To make a pair of stereo projections, each set of 5 optical sections was projected to form a single image for each eye. While forming the projection for the left-eye, images were sequentially shifted by 1 pixel to the left, whereas right eye images were shifted 1 pixel to the right. As the optical sections are separated by 1 μm, a shift by one pixel (0.17 μm) per every section (1 μm) corresponds to a tilt of 9.6°, therefore the stereo pair is separated by a tilt of 19.2°. To remove out-of-focus information from the projected images, a three-dimensional optical transfer function was experimentally determined for the objective lens under the conditions used for the data collection of nuclei by imaging very small fluorescent beads (0.1 μm in diameter) as described previously[5]. The projected stereo images were computationally processed to remove out-of-focus information by a constrained iterative deconvolution method using the $Z^* = 0$ plane of the three-dimensional optical transfer function[4]. This approach, based on the Fourier projection theorem, can provide nearly perfect signal recovery using data collection conditions that cause minimum exposure to the specimen. Although not precisely correct for the sliding stereo projections used here, the approximation is suitable for the limited spatial regions examined. For rapid movie display, the entire set of time-lapse stereo images was loaded into the Parallax display system with a 12 Mbyte image memory before the display. This permits a pair of the stereo projection images to be displayed side-by-side and rapidly unpdated to form a time-lapse stereographic movie.

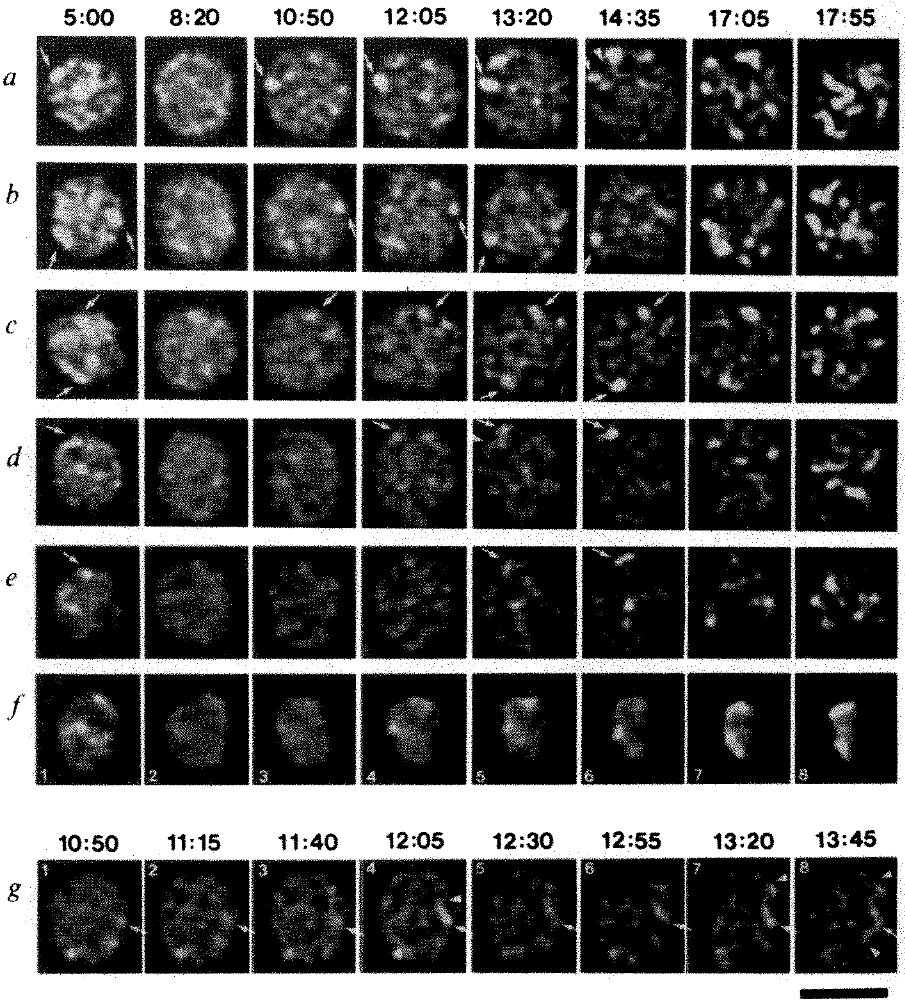

FIG. 2 Chromosome decondensation and condensation. Chromosome decondensation and condensation is shown as a time course. Only one view of the stereo movie is shown for each time point. A damaged nucleus is shown in *f*. Chromosome fibres growing in a single nucleus shown in *g* at every 25 s from 10 min 50 s to 13 min 45 s. The numbers at the top of each column or frame represent time in minutes:seconds as in Fig. 1. Nucleation sites are shown by arrows and fibres by arrowheads. Scale bar represents 5 μm.

appear over a 5-minute interval (Fig. 2*a*–*e*, columns 3–6). Significantly, the relative positions of these early condensation sites were similar to those of the late decondensation sites. Examples of the congruity as shown in Fig. 2*a*–*e* (compare column 1 with columns 3–6). In addition, newly condensed chromosome 'fibres' can be seen elongating from these sites at the rate of about 1 μm per min (Fig. 2*a*, *d* and *g*). In one particularly clear case (Fig. 2*g*), the elongation appears to be bidirectional. As the condensation sites were found near the nuclear midline, they are unlikely to be either centromeric or telomeric sites, which are known to be localized to the apical and basal portions of the nucleus respectively[9]. Towards prophase (Fig. 2*a*–*e*, columns 7, 8), the chromosomes are seen to condense further, forming more contiguous structures. By the time condensation has proceeded sufficiently to identify individual chromosomes, the sites have detached and moved from the nuclear envelope (compare columns 6 and 7 in Fig. 2*a*–*e*), making it impossible to assign these sites, as yet, to specific chromosomes.

Similar chromosomal bright spots were observed in higher-resolution optical section data of nuclear-cycle-13 embryos that had been fixed and stained with the DNA-specific fluorescent dye, 4′,6-diamidino-2-phenylindole (DAPI), as shown in Fig. 3. Below the nuclear midline, chromosome condensation sites were exclusively observed at the nuclear envelope. By contrast, sites were seen both internally and at the periphery above the midline. It seems that the internal bright spots are associated with, and likely to be a part of, the centrometric heterochromatin. Although such peripheral bright spots had been repeatedly observed in fixed preparations in our laboratory, it is only as a result of continuous observation of chromosome behaviour in individual nuclei that we appreciated the significance of these chromosomal regions.

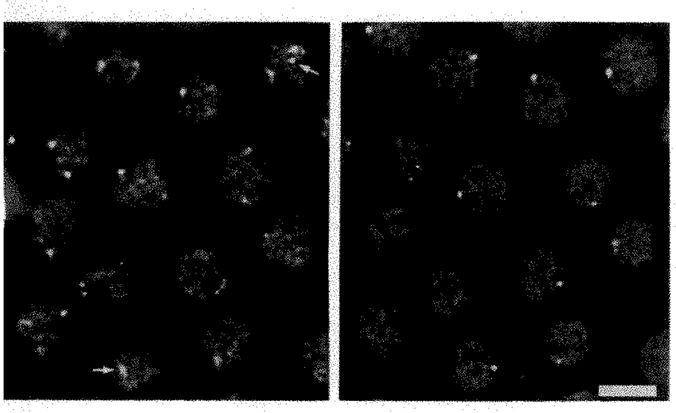

FIG. 3 Sites of condensed chromatin in fixed nuclei. Two optical section images are shown, separated by 2 μm, from a high-resolution three-dimensional data set of a fixed embryo. Because of the curvature of the embryo surface, the focal plane intersects nuclei seen in the upper and lower portions of the field at higher positions than those located in the centre of the field. All of the nuclei shown in the left panel are visualized above the nuclear midline, whereas those in the right panel are all at, or below, the midline. Arrows indicate apparent intranuclear sites above the midline. Scale bar represents 5 μm.

METHODS. *Drosophila* embryos were fixed with 3.7% formaldehyde in heptane/buffer A (15 mM PIPES, pH 7.0, 80 mM KCl, 20 mM NaCl, 0.5 mM EGTA, 2 mM EDTA, 0.5 mM spermidine, 0.2 mM spermine, 0.1% 2-mercaptoethanol). The chorion and vitelline membrane were removed as described previously[17]. The embryos were stained with 0.1 μg ml^{-1} DAPI. Optical section images were collected on the CCD at focus step of 0.2 μm using an Olympus oil-immersion objective lens (60×/NA1.4) and computationally processed to remove the out-of-focus information as described[4].

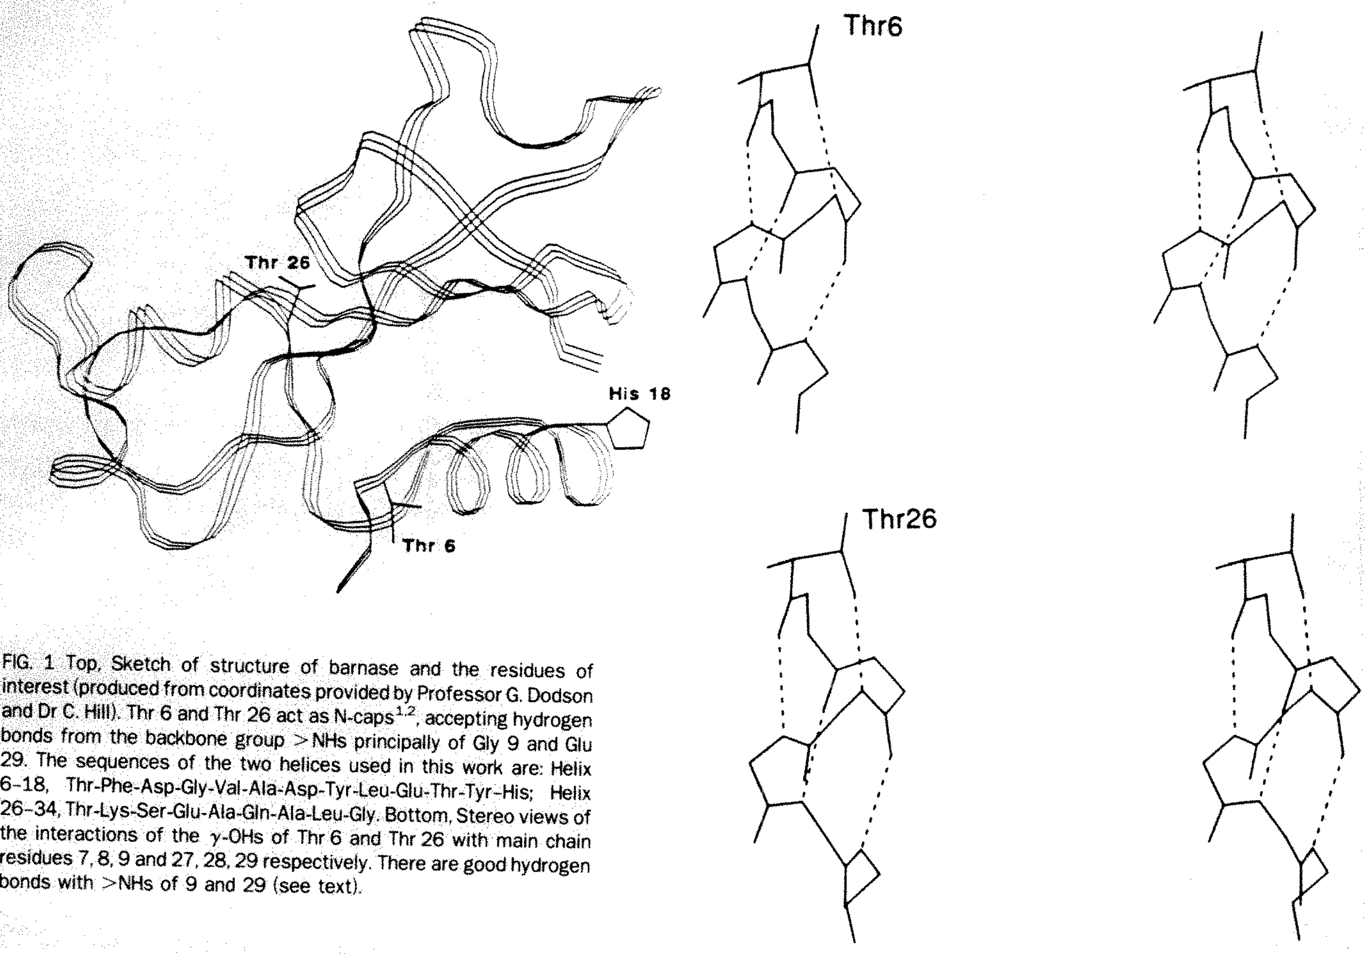

FIG. 1 Top, Sketch of structure of barnase and the residues of interest (produced from coordinates provided by Professor G. Dodson and Dr C. Hill). Thr 6 and Thr 26 act as N-caps[1,2], accepting hydrogen bonds from the backbone group >NHs principally of Gly 9 and Glu 29. The sequences of the two helices used in this work are: Helix 6–18, Thr-Phe-Asp-Gly-Val-Ala-Asp-Tyr-Leu-Glu-Thr-Tyr-His; Helix 26–34, Thr-Lys-Ser-Glu-Ala-Gln-Ala-Leu-Gly. Bottom, Stereo views of the interactions of the γ-OHs of Thr 6 and Thr 26 with main chain residues 7, 8, 9 and 27, 28, 29 respectively. There are good hydrogen bonds with >NHs of 9 and 29 (see text).

wild-type and mutant proteins[5-8]. Barnase contains two α-helices[9], one from residues 6 to 18 and the other from 26 to 34 (Fig. 1). Both α-helices begin with a threonine residue as N-cap (the first residue in the helix[2], namely Thr 6 and Thr 26, Fig. 1), but the overall composition of the rest of each helix is quite different. The -OH groups of Thr 6 and Thr 26 are positioned so that the oxygen atom may act as a hydrogen bond acceptor from the backbone > NH groups of residues 7 or 27, 8 or 28 and 9 or 29 (N1, N2 and N3 in the Richardson[2] nomenclature). The geometry for hydrogen bonding from the -OH of residues 6 and 26 is good with respect to residues 9 and 29, fair for 8 and 28 and poor for 7 to 27 (Table 1), which is usual with N-caps[2]. The C_γ and C_β of both threonines participate in further interactions in the protein (Table 1). Here we use inferences from recent surveys of helix structure[1,2] to design changes in both barnase helices to give precise information on how hydrogen bonding, and electrostatic[10] and other interactions at the N-terminus of a helix affect its stability.

The most common residues found at the N-cap position of helices are: Ser, Asn, Gly, Asp and Thr[2]. The residues Ala, Leu, Val, Ile, Trp, Arg, Gln and Glu are found rarely[2]. We substituted Thr with the following residues: with Gly, Ala and Val to measure the effect of losing hydrogen bonds from the γ-OH to the > NH groups of the helix and to assess the influence of a different size of side chain; with Ser to measure the loss of hydrophobic interactions from the γ-methyl; with Asn and Gln to determine the effects of substituting the carboxyamide oxygen of each of the γ-OH as a hydrogen bond acceptor, and with Asp and Glu to establish the effects of a charged hydrogen bond acceptor. Two mutants, Thr 26 → Asp and Thr 6 → Val, could not be expressed, despite numerous attempts using this expression system[11].

Mutation of either Thr 6 or Thr 26 at the N-caps of each helix in barnase gives quite similar changes in stability and consistent trends (Table 2). Considering that the two helices have different compositions and environments, the results are not specific to a particular helix and so presumably report on some general features. A fine-structure analysis can be made by comparing pairs of mutants that differ by just a small change.

Thr → Ser. Mutation of Thr 6 → Ser causes the loss of 0.22 kcal mol^{-1} and Thr 26 → Ser, 0.56 kcal mol^{-1} of stabilization energy (Table 2). The $C\gamma$ of Thr 6 and 26 make van der Waals' contacts with the protein (Table 1), and so this contribution to the stabilization is lost. It should be noted that none of these contacts is within the helix. Thus, the advantage of having a threonine rather than a serine at the N-cap seems to depend mainly on the existence of tertiary interactions elsewhere in the structure, and not on interactions within the helix itself. These interactions will vary from protein to protein.

Ser → Gly, Ala or Val. Naïve reasoning would suggest that mutation of Ser → Ala might give an empirical measurement of energy change due to the loss of the hydrogen bonds from the -OH to the backbone > NH groups, and Ala → Gly, a measure of the loss of the van der Waals' energy from the β-methyl group. Mutation of Ser 6 → Ala loses 2.3 kcal mol^{-1} or 1.6 kcal mol^{-1} for replacement of Ser 26 (Table 2). But, mutation of Ser → Gly loses only 1 kcal mol^{-1}. Thus, Gly is more stable than Ala at the N-cap by 0.5–1 kcal mol^{-1}. In general, Ala is energetically preferred to Gly in the helix, except at the N-cap[12], either because of the greater entropic freedom of glycine-containing peptides in the denatured state[13], or because of hydrophobic interactions of the alanine β-methyl group in the helix. Why then is Gly preferred to Ala at the N-cap? We suggest that one contributing factor is that the β-methyl group of Ala sterically interferes with solvation of the >NH groups at the N-terminus of the helix—Gly allows more space for optimal hydrogen bonding by water. Consistent with this notion is that Thr 26 → Val is the most destabilizing mutation, despite the retention of the γ-methyl group with its potential for hydrophobic interactions worth ~0.6 kcal mol^{-1}. The large side chain of Val makes solvation of the >NH groups by water difficult. These results parallel statistical data on the frequency of residues at the N-cap (Table 3). There is evidence elsewhere that an uncharged hydrogen bond contributes some 0.5-1.5 kcal mol of stabilization energy to a complex[14]. The apparent binding energy of the N-cap hydrogen bond from Ser to the >NH groups is in this region.

Thr → Asn, Gln. The previous mutations are relatively easy to interpret in the absence of detailed crystal structures of the mutants because interactions were deleted without introducing new ones, and so the necessary structural information is present in the crystal structure of the wild type. Substitution with Asn, Asp (or Glu or Gln), adds the possibility of further interactions that can obscure simple interpretation. Statistically, Asn is one of the most favourable residues at the N-cap of helices[2]. The carbonyl oxygen of the side chain can act as a hydrogen bond acceptor of the backbone >NH groups. On the other hand, Gln and Glu are rarely found at the N-cap as their side chains cannot make good hydrogen bonds to the backbone >NH groups[2]. Mutation of Thr → Gln in positions 6 to 26 results in destabilizing the protein by 1.9 and 1.7 kcal mol^{-1} respectively. But Thr → Asn also destabilizes both helices by 1.3 kcal mol^{-1}. The reason for this is not obvious, because Asn can be built into the structure with its carbonyl oxygen placed to accept hydrogen bonds from the backbone >NH groups and its own $-NH_2$ group exposed to water. Perhaps Asn is not inherently as good an N-cap as Ser or Thr, but may be better when the $-NH_2$ group can hydrogen bond elsewhere in the protein. There should be more protein structure surveys undertaken to look for other factors. Whatever the explanation, Asn is not necessarily a good choice for the N-cap of an helix.

Thr → Asp, Glu. Mutation of Thr 6 → Asp stabilizes the protein by 0.1 kcal mol^{-1}, but Thr 6 → Glu destabilizes it by only 0.3 kcal mol^{-1} and Thr 26 → Glu destabilizes it by less than 0.1 kcal mol^{-1}, despite the low frequency of Glu at the N-cap[2]. The α-helix possesses a macroscopic dipole with its positive pole at the N-terminus[10]. Recent studies have suggested values of about 1.4-2.1 kcal mol^{-1} for the interaction energy of a single charge with the dipole of a helix[6,15]. A charge-dipole electrostatic interaction is the probable reason for the stability of the mutants with Asp and Glu. Comparison of Asp with Asn and Glu with Gln gives another estimate of the importance of the charge-dipole interaction: Asp 6 → Asn gives 1.4 kcal mol^{-1}; Glu 6 → Gln, 1.6 kcal mol^{-1}; and Glu 26 → Gln, 1.6 kcal mol^{-1}. These results are strikingly similar to those of the earlier studies, despite

Asn → Gln	0.60	0.43
Ser → Ala	2.31	1.55
Ser → Gly	1.12	1.02
Gly → Ala	1.19	0.53

* $\Delta\Delta G_U$ is the free energy of unfolding of wild-type enzyme minus that of mutant. The free energies of unfolding of wild-type protein and mutants were analysed by urea denaturation monitored by fluorescence[5-7]. This analysis is based on the equation $\Delta G_U = \Delta G_U^{H_2O} - m[\text{Urea}]$, where ΔG_U is the free energy of unfolding in urea solution, $\Delta G_U^{H_2O}$ the free energy of unfolding in water, and m is a constant. We find that there is little difference in calculating $\Delta\Delta G_U$ directly by comparing ΔG_U for wild type and mutant at the same concentration of urea[5] or by using the simpler procedure[7] of $\Delta\Delta G_U = \langle m\rangle(\Delta[U]_{1/2})$, where $\Delta[U]_{1/2}$ is the concentration of urea at which wild type is 50% denatured, minus the concentration of urea at which the mutant is 50% denatured. The average value of m for wild type and mutant is denoted by $\langle m\rangle$. We find that m does not deviate by more than 10% of a mean value which is 2.23 (±0.02 standard error) kcal mol^{-2} for all mutants. $[U]_{1/2}$ never differs by more than 1% (< ±0.04 M) for experiments performed over a period of time and is generally reproducible to ±0.01 M with identical batches of urea. The data are probably reliable to ±0.02 kcal mol^{-1}. As the free energy of unfolding determined by either method is essentially the same, we have used the second method method to obtain the values of the free energy of unfolding of all the proteins.

Proteins were prepared by an improved procedure. Wild-type enzyme was secreted from *E. coli* BL21DE3 pLysS (ref. 16) harbouring the barnase gene construction[12] on the pTZ18u plasmid (Pharmacia). Cells were grown in low-phospate medium[17] and the expression of barnase was induced by the addition of 0.5 mM isopropyl-β-D-thiogalactoside following the conditions described by Studier *et al.*[16]. After further growth for 2.5 h, the protein was purified as before[18]. For site-directed mutagenesis we used the method of Eckstein *et al.*[19]. Mutants were identified either by direct sequencing of single-stranded DNA or after previous screening by the hybridization method[20].

TABLE 3 Comparison of statistical and energetic surveys of N-cap stabilities

Preferred residue at N-cap	Stabilization energy relative to Thr (kcal mol^{-1})*	Frequency at N-cap†	Relative value‡
Asp	−0.1	27	2.1
Thr	0.0	21	1.6
Glu	0.2	5	0.4
Ser	0.4	34	2.3
Asn	1.3	34	3.5
Gly	1.5	33	1.8
Gln	1.8	3	0.4
Ala	2.3	10	0.5
Val	2.3	1	0.1

* Average value at positions 6 and 26.

† Frequency found in survey in ref. 2.

‡ Frequency at N-cap normalized for frequency of occurrence in proteins in general[2].

there being an unfavourable electrostatic interaction at position 6 with the negative charge on Asp 8. As so many different substitutions with different hydrogen bonding patterns and at different ends of the helix give similar values, the estimate of 1.4–2.1 kcal mol^{-1} for the helix–charge interaction is valid.

There is a very rough parallel between the energetics of N-cap formation and statistical surveys of the frequencies found in practice (Table 3). Notable exceptions, however, are Asn and Glu. Our data indicate that Glu is quite acceptable at the N-cap, being only marginally less stable than Thr. Asn is statistically over-represented, given the data in this study.

In conclusion, the N-cap is important to stability and substitution of selected residues can cause an energy change of over 2 kcal mol^{-1}. It is clear, however, that when designing a helix, the choice of residue depends on the context of the overall tertiary structure—that is, on interactions with residues removed in sequence but stereochemically close to the helix. Even so, it seems that some residues are particularly favourable. For example, Ser is inferior to Thr only when hydrophobic interactions are favourable for the γ-methyl group. For barnase, the Ser mutants are only 0.2 to 0.6 kcal mol^{-1} less stable, although the methyl group can be worth up to 1.5 kcal mol^{-1} when packing is particularly good[5,7]. In other circumstances, steric exclusion of the γ-methyl group would prohibit the use of Thr. Asp is clearly the best for an exposed N-terminus that has no adjacent negative charges. ☐

X-ray analysis of HIV-1 proteinase at 2.7 Å resolution confirms structural homology among retroviral enzymes

KNOWLEDGE of the tertiary structure of the proteinase from human immunodeficiency virus HIV-1 is important to the design of inhibitors that might possess antiviral activity and thus be useful in the treatment of AIDS[1]. The conserved Asp–Thr/Ser–Gly sequence in retroviral proteinases[2] suggests that they exist as dimers similar to the ancestor proposed for the pepsins[3–5]. Although this has been confirmed by X-ray analyses of Rous sarcoma virus and HIV-1 proteinases[6,7], these structures have overall folds that are similar to each other only where they are also similar to the pepsins[8]. We now report a further X-ray analysis of a recombinant HIV-1 proteinase at 2.7 Å resolution. The polypeptide chain adopts a fold in which the N- and C-terminal strands are organized together in a four-stranded β-sheet. A helix precedes the single C-terminal strand, as in the Rous sarcoma virus proteinase[6] and also in a synthetic HIV-1 proteinase, in which the cysteines have been replaced by α-aminobutyric acid[9]. The structure reported here provides an explanation for the amino acid invariance amongst retroviral proteinases, but differs from that reported earlier[7] in some residues that are candidates for substrate interactions at P_3, and in the mode of intramolecular cleavage during processing of the polyprotein.

To obtain HIV-1 proteinase for crystallization, a recombinant fragment of the viral *pol* gene was expressed in *E. coli* as described in the legend to Fig. 1. Crystals, prepared using the published protocol[10], grew at 4 °C in five days. X-ray data were collected from a tetragonal bipyramidal crystal to 2.7 Å resolution using a FAST area detector. Earlier, we constructed models using Composer[5], initially from the pepsins and later from the Rous sarcoma virus (RSV) structure. From these we constructed a model for use in molecular replacement that did not include the N- or C-terminal strands, the helix or the flap, the positions of which were uncertain. A series of difference Fourier analyses, modelling, and refinement steps gave first the region 47 to 54 (the flap), then the N- and C-termini, and finally the turn after the N-terminal strand (residues 5 to 11) and the α-helix (residues 87 to 93). In each case the polypeptide could be followed in the difference electron density (calculated on the basis of a model in which they had not previously been included) without a break and with clear positions for the side chains (Fig. 1). Thus we achieved an unequivocal tracing of all 99 residues of the polypeptide chain. Further details of the analysis and refinement are given in the legend to Fig. 1. The final geometry has a 0·019 Å r.m.s. deviation from idealized geometry and the present agreement value is 18.9%.

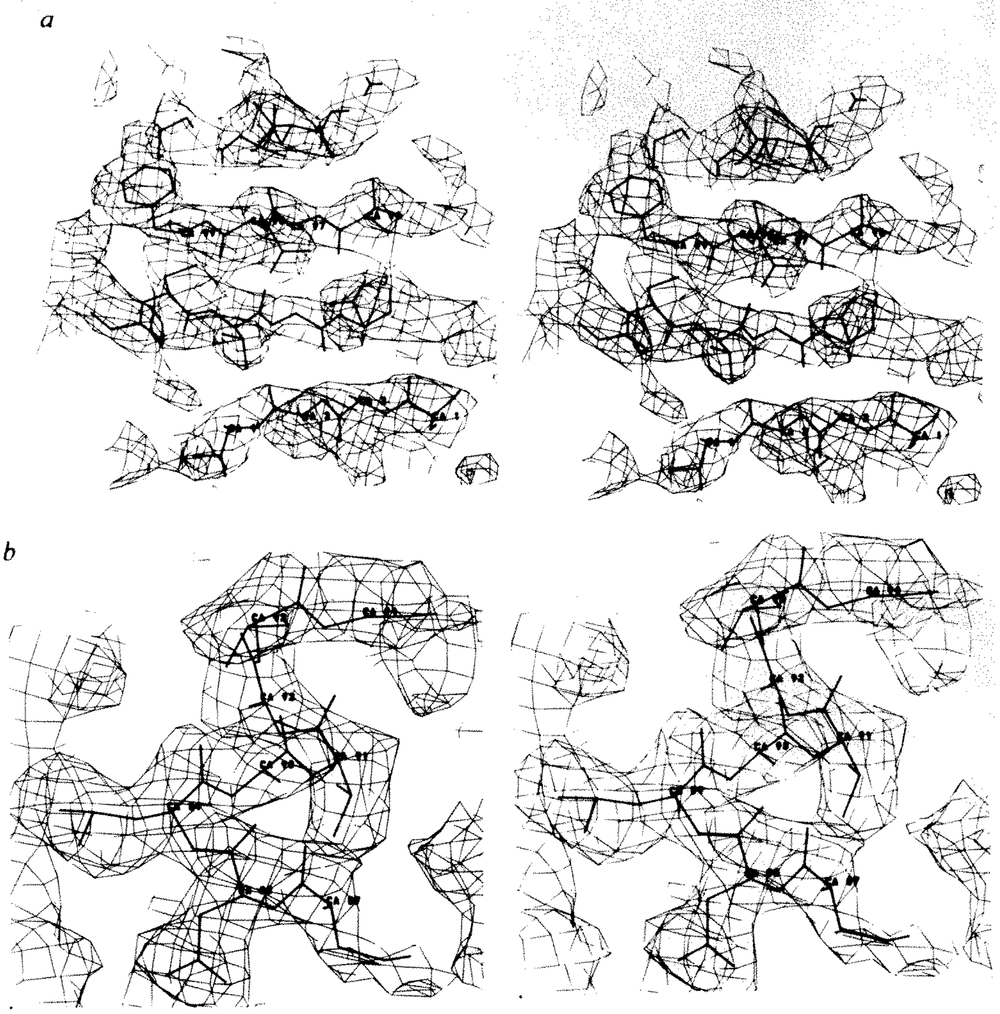

FIG. 1 Stereo views of difference electron density maps calculated with coefficients $2F_{obs} - F_{calc}$ for *a*, the intermolecular four-stranded, antiparallel β-pleated sheet involving the N-terminal and C-terminal strands (a and t) and *b*, residues 87 to 90 which form part of the helix, h′, preceding the terminal strand, t; the strands and helices here are defined in the legend to Fig. 2 and were omitted from the calculation of phases used in the difference Fouriers.

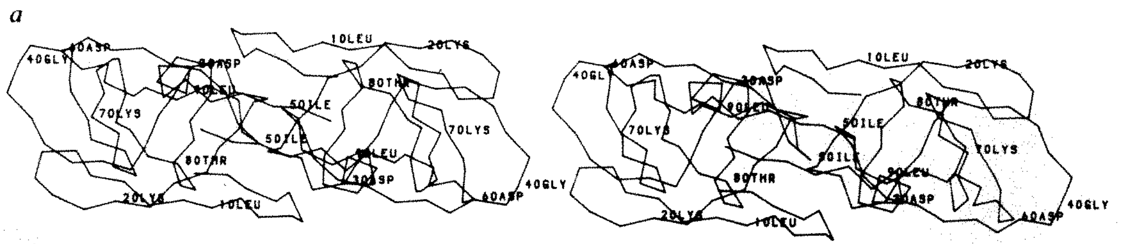
METHODS. Enzyme for crystallization was expressed in *E. coli* as follows. The bacterial expression plasmid pHIVexpol5 was constructed by subcloning the 5.0 kilobase *Bgl*II fragment from the pHXBc2 clone of the viral genome[18] into the *Bgl*II-cleaved derivative of pPFZ-R2 (ref. 19). This gave a gene controlled by the *trp* promoter and encoding a fusion polypeptide comprising an initiator methionine, a 7-residue junction sequence Ala-Glu-Ile-Thr-Arg-Ile-Glu-, and a fragment of the *pol* gene product which had a relative molecular mass of 115,000 (115K) which encompassed the proteinase, reverse transcriptase and integrase domains. *E. coli* MM294 cells harbouring pHIVexpol5 were shown by western blotting and immunodetection to produce appropriately processed proteinase (11K). HIV-1 proteinase was purified from the soluble fraction of cell lysates (D.E.D. *et al.*, manuscript in preparation) to give a single band on Coomassie blue-stained SDS-polyacrylamide gels. Automated Edman degradation gave an N-terminal sequence of Pro-Gln-Ile-Thr-Leu-, consistent with the expected result of self-processing of the *pol* gene product. The purified proteinase recovered per litre of bacterial culture was 0.25 mg. The specific activity of the purified enzyme was measured using a 17-residue synthetic peptide substrate (RRVTNSATIMMQRGNFR (one-letter code); J. Schneider, personal communication), and was estimated at 2.4 μmol substrate cleaved per min per mg of proteinase at pH 5.5, 23 °C and 0.2 mM substrate. Details of the expression studies, cell growth and protein purification will be presented elsewhere (D.E.D. *et al.*, manuscript in preparation). Crystals, isomorphous with those reported earlier[7] of space group $P4_12_12$, were used for FAST area detector data collection, giving 10,000 reflections over a period of two days. A merging *R*-value was 0.11 leading to over 2,200 reflections with $I > 2.0\sigma(I)$, with a maximum resolution of 2.7 Å. Refinement of the initial model using rigid group refinement was achieved using RESTRAIN[20] using the CRAY XMP/28 at University of London Computing Centre. In the final cycles, we used individual thermal parameters but tight geometric restraints. Difference Fouriers calculated with coefficients $2F_{obs} - F_{calc}$ and $F_{obs} - F_{calc}$ were displayed simultaneously using FRODO[21] on an Evans and Sutherland PS390. The model was extended in steps to include the N- and C-termini and the helix and at each stage refined using restrained least squares.



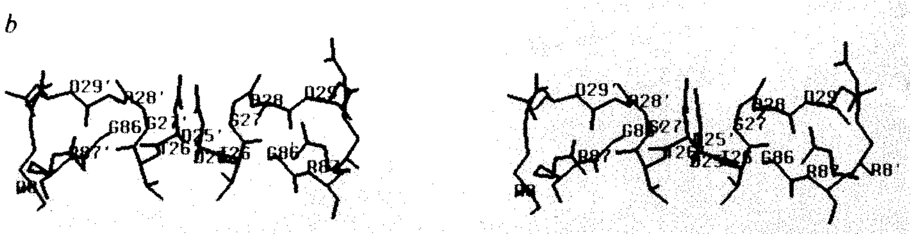


FIG. 2 Stereo views of *a*, C_α atoms viewed from the side of the dimer containing the four-stranded β-sheet and along the twofold axis relating subunits in the dimer, and *b*, conserved residues of the active-site cleft (Asp 25, Thr 26, Gly 27, Asp 29 and Arg 87) which are organized around the twofold axis of the dimer and are thought to be involved in substrate recognition and catalysis.

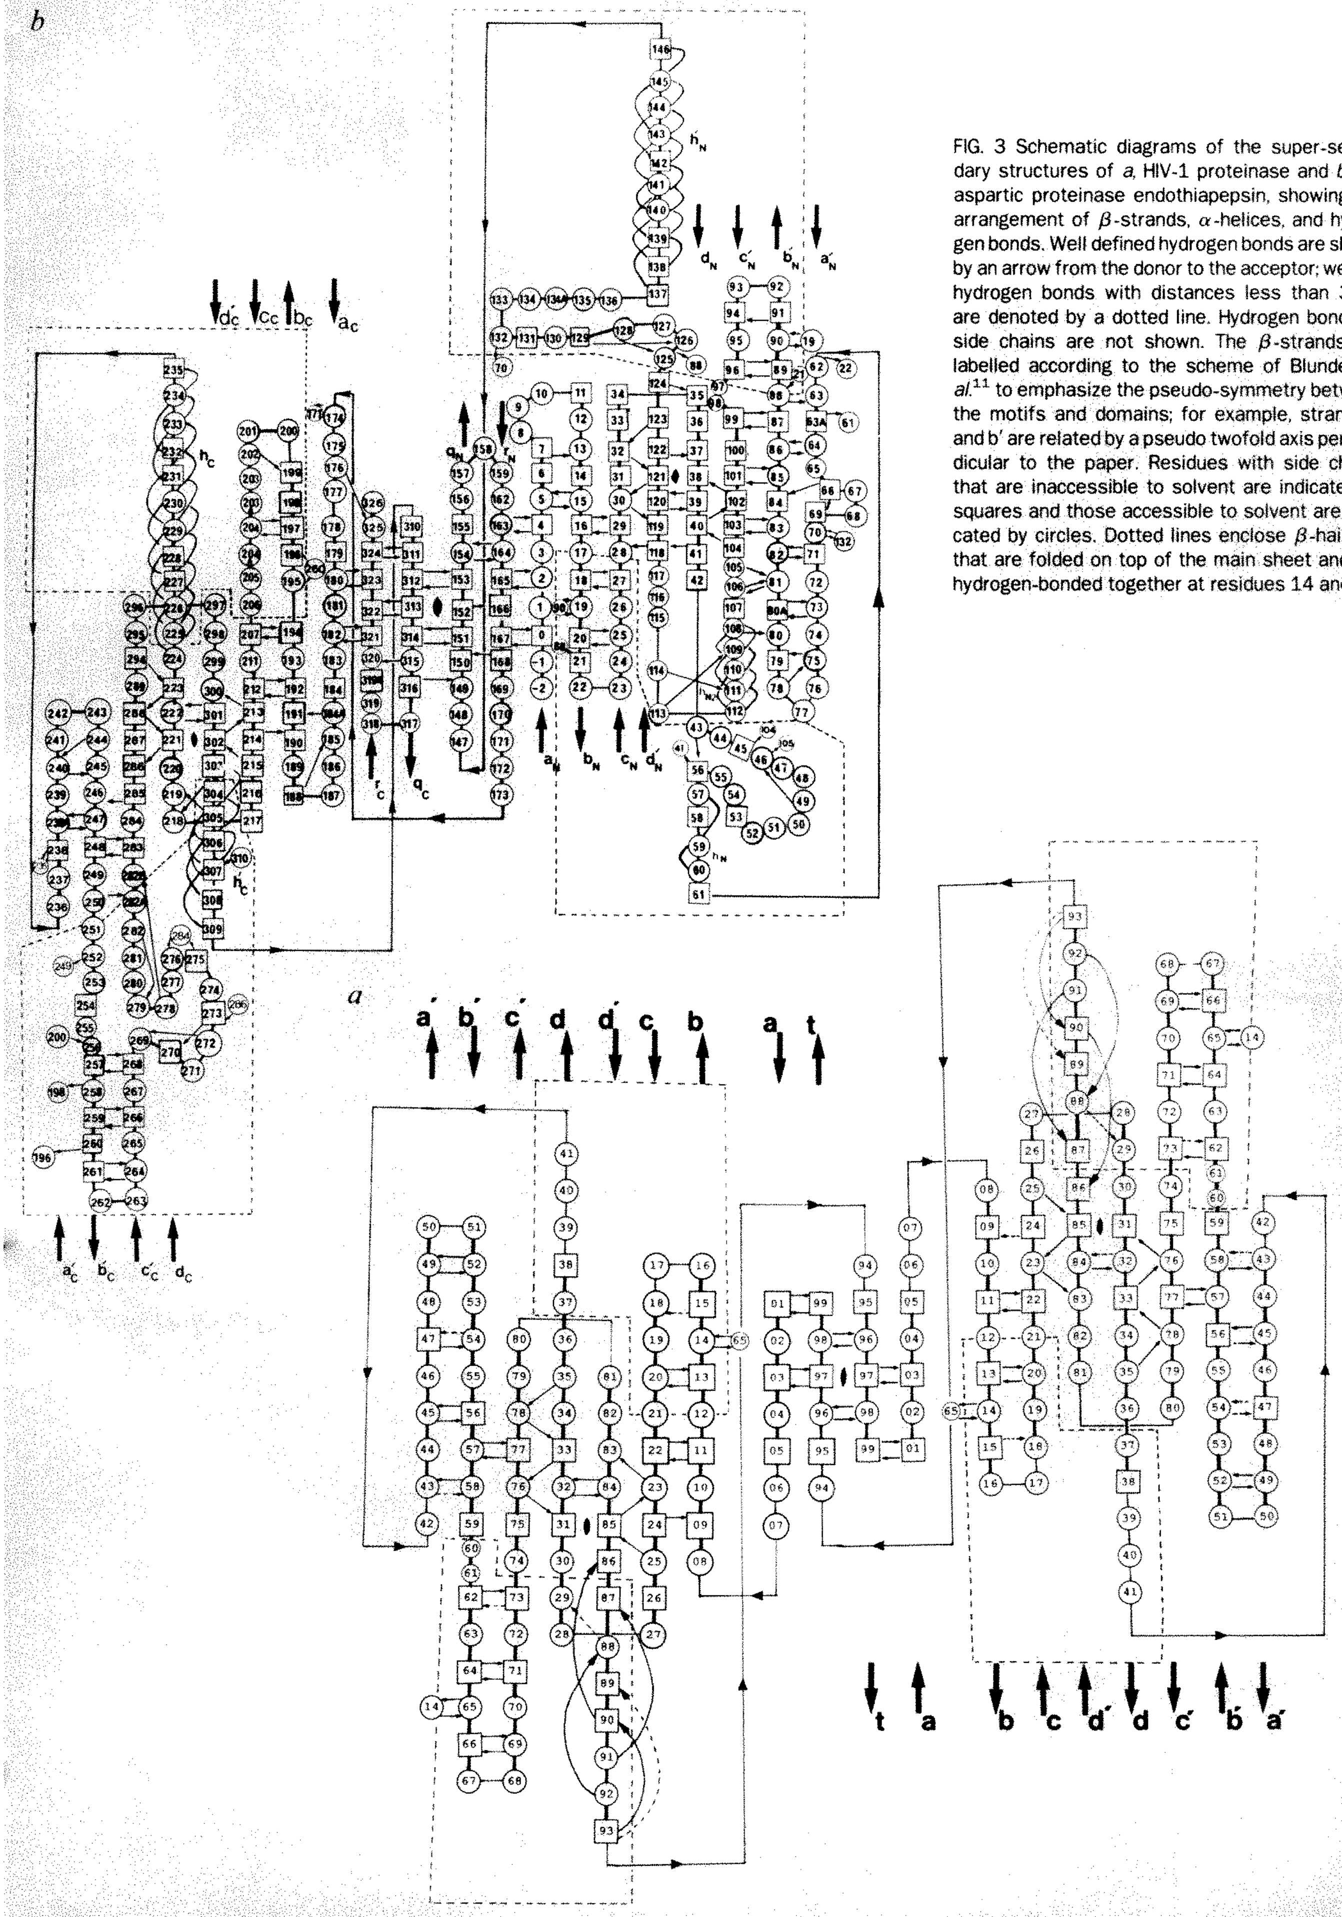

FIG. 3 Schematic diagrams of the super-secondary structures of *a*, HIV-1 proteinase and *b*, the aspartic proteinase endothiapepsin, showing the arrangement of β-strands, α-helices, and hydrogen bonds. Well defined hydrogen bonds are shown by an arrow from the donor to the acceptor; weaker hydrogen bonds with distances less than 3.9 Å are denoted by a dotted line. Hydrogen bonds to side chains are not shown. The β-strands are labelled according to the scheme of Blundell *et al.*[11] to emphasize the pseudo-symmetry between the motifs and domains; for example, strands b and b′ are related by a pseudo twofold axis perpendicular to the paper. Residues with side chains that are inaccessible to solvent are indicated by squares and those accessible to solvent are indicated by circles. Dotted lines enclose β-hairpins that are folded on top of the main sheet and are hydrogen-bonded together at residues 14 and 65.

Figure 2 shows stereo views of the three-dimensional structure of the enzyme, which exists as a dimer with a well defined and extensive active-site cleft. Figure 3 shows the secondary structure and hydrogen bonding in the dimeric structure compared with that of a pepsin. We adopt the strand nomenclature[11] suggested for endothiapepsin. Each subunit comprises two similar motifs related by an approximate twofold axis; each motif contains anti-parallel strands: a, b, c and d for the first and a', b', c' and d' for the second. These are organized together in a distorted sheet, with strands c and d' and strands c' and d forming two pairs of parallel strands (Fig. 3). Strands b and c and strands b' and c' form antiparallel β-hairpins which are folded on top of the first sheet and hydrogen-bonded together around the same twofold axis that relates the motifs in the main sheet. The strands d and d' are followed by an irregular region and an α-helix, respectively, which also lie on the same side of the main mixed β-sheet. Strand a of the first motif is displaced from the main mixed sheet and forms an antiparallel four-stranded β-sheet with the terminal strand, t, and the two equivalent strands from the other subunit of the dimer. These strands occupy the same volume but have different orientations from the six-stranded β-pleated sheet that connects the two domains of the pepsins (Fig. 3*b*).

The structure corresponds closely to the arrangement of the completely symmetrical dimer that has been proposed as the ancestor of the aspartic proteinases[3]. The conserved active site residues, Asp 25–Thr 26–Gly 27, form a symmetrical and highly hydrogen-bonded arrangement virtually identical to that described for pepsins[12,13]. The two threonines are inaccessible to solvent and are hydrogen-bonded so that the O-gamma bonds to main-chain N–H and C=O functions of the other subunit in a fireman's grip. The two aspartates lie roughly coplanar, with their inner carboxylate oxygens hydrogen-bonded to the N–H functions of Gly 27. There is density for a water molecule bound equally to the two carboxylates, as found in pepsins.

An extensive hydrophobic core involving residues indicated by squares in Fig. 3 extends through the dimeric interface. Pro 1, Ile 3 and Leu 5 of the N-terminal strand, and Cys 95, Leu 97 and Phe 99 of the C-terminal strand, form one side of the central four-stranded β-pleated sheet and pack onto Leu 24 and Thr 26 adjacent to the catalytic residues and the hydrophobic residues of the helix, such as Leu 89, Leu 90 and Ile 93. These residues of the core tend to be highly conserved amongst the retroviral proteinases, giving support to this interpretation of the structure. The only truly buried polar residue apart from Thr 26 is Thr 31, which is also hydrogen-bonded to main-chain N–H and C=O functions in a fashion that is often important to protein structure. Thr 31 is either retained as threonine or occasionally conservatively varied to serine in retroviral proteinases.

One of the significant conservations in the consensus sequences of the retroviral and pepsin-like aspartic proteinases is an amino-acid sequence of two hydrophobic residues followed by a glycine, an example of which is the sequence Ile 84–Ile 85–Gly 86 that is found in HIV-1 proteinase. The retroviral proteinases differ, however, in the presence of an invariant arginine in the next position, for example Arg 87. Such a basic residue is never found in the pepsins. The crystal structure of HIV-1 proteinase shows that this conserved arginine participates in an intersubunit cluster of ionic and hydrogen bonding interactions involving the side chains of the conservatively varied Asp 29 and Arg 8, as in RSV proteinase[6]. No reason for the conservation of these residues is apparent from the structure reported by Navia *et al.*[7]. It is also apparent that the N-terminus is well organized in the dimer and so flexibility cannot be involved in the precursor autocleavage[7].

The close similarity of the three-dimensional structures of the dimeric retroviral proteinases and the monomeric pepsins suggests a common mode of interaction with substrate. X-ray studies of aspartic proteinase transition-state isostere complexes[14–16] show that the substrate probably binds pseudo-symmetrically in the active-site cleft, using topologically equivalent hydrogen bonding functions and specificity pockets on each side of the scissile bond. By analogy, the carbonyls of Gly 27 in HIV-1 proteinase may form hydrogen bonds to the substrate N–H functions of P_1 and P_2', as suggested by Blundell and Pearl[8] and by Wlodawer and coworkers[17]. The conservatively varied but exposed Leu 23, Ala 28, Val 82 and Ile 84 form the large S_1/S_1' specificity subsites. By analogy with the aspartic proteinases, in which P_3 binds through its main chain to the side-chain oxygen and the main-chain N–H of Thr 219 (pepsin numbering), these interactions would be mediated by Asp 29 in HIV-1 proteinase. This gives further support to the importance of the cluster of charged residues involving Asp 29; the charged residue Arg 87 contributes to the correct orientation of the carboxylate group (Fig. 2*b*). The pocket, S_3, in this HIV-1 proteinase structure differs from that reported earlier[7] in that it involves the loop between strands a and b.

The perfectly symmetrical structure of the retroviral proteinases lends credence to the suggestion[13] that the apparently differing pK_as of the two aspartates in aspartic proteinases are more a function of their proximity than of their differing environments. Nevertheless, the symmetrical dimer must lose its perfect symmetry during catalysis as the substrate has only an approximate dyad. But this is not a restriction for inhibitors, so symmetrical structures may have a major advantage in high affinity binding when compared with an analogous substrate. ☐

PHYSICAL PROPERTIES OF HIGH TEMPERATURE SUPERCONDUCTORS I

edited by D M Ginsberg (Univ. Illinois, Urbana-Champaign)

While a great effort has been made to discover new high temperature superconductors, a large-scale, parallel effort has been made to determine the fundamental properties of these fascinating new materials. This is perhaps one of the best books in the field describing these vital properties in an organized and comprehensive manner.

528 pp Mar 1989 9971-50-683-1(US$84)H/C 9971-50-894-X(US$44)S/C

PHYSICAL PROPERTIES OF HIGH TEMPERATURE SUPERCONDUCTORS II

editd by D M Ginsberg (Univ. Illinois, Urbana-Champaign)

This volume will contain chapters on some of the major areas of activity which were not covered extensively in Volume 1: structure, microstructure, thermodynamics, oxygen stoichiometry effects, nuclear magnetic and quadrupole resonance, transport of charge and heat, photoemission, microwave properties, films, and the pairing state. This book should be useful to all students, scientists, and engineers who desire to know more about high temperature superconductivity.

ELEMENTARY SYMBOLIC DYNAMICS AND CHAOS IN DISSIPATIVE SYSTEMS

by Hao Bailin

This is a monograph on chaos in dissipative systems written for those working in the physical sciences. Emphasis is on symbolic description of the dynamics and various characteristics of the attractors, and written from the view-point of practical applications without going into formal mathematical rigour. Substantial attention is paid to numerical techniques in the study of chaos.

New Books from C·A·B International

THE STATUS OF ANIMALS: Ethics, Education and Welfare

Edited by David Paterson and Mary Palmer, formerly of the British Veterinary Association Animal Welfare Foundation

Of interest to philosophers, teachers, veterinary and agricultural scientists and many lay people, this book covers farming, animal experimentation; human-animal interactions; the role of the veterinarian; animals and the media; and education.
(September 1989) 268 pages ISBN 0 85198 650 1
£12.50 UK US$23.50 Americas £13.75 Elsewhere

EVOLUTION AND ANIMAL BREEDING: Reviews on molecular and quantitative approaches in honour of Alan Robertson

Edited by W G Hill, University of Edinburgh and T F C Mackay, North Carolina State University

Contains 36 commissioned chapters covering Population genetics and evolution, Genetics of metric traits, Quantitative approaches to animal breeding, and Genetic manipulation and animal breeding. Contributors include R C Lewontin, M Kimura, J Maynard Smith, B Charlesworth, D S Falconer and other world authorities.
(July 1989) 328 Pages ISBN 0 85198 639 0
£45.00 UK US$84.00 Americas £49.50 Elsewhere

CYTOGENETICS OF ANIMALS

Edited by C R E Halnan, University of Sydney

A major well-illustrated text which will serve as a workshop manual, reference to modern techniques, guide to terminology, compendium of standard karyotypes and a handbook for the interpretation of data.
(October 1989) 570 pages ISBN 0 85198 629 3
£65.00 UK US$121.50 Americas £71.50 Elsewhere

OPPORTUNISTIC MYCOSES OF MAN AND OTHER ANIMALS

J M B Smith, University of Otago

A source work for mycopathologists and veterinarians, bringing together data on fungi able to establish themselves on susceptible hosts, including immunosuppressed patients. Reviews important aspects of the pathogenesis of the resultant diseases and provides routes into the dispersed literature on this topic.
(September 1989) 230 pages ISBN 0 85198 638 2

YOUR WEEKLY BIOMEDICAL UPDATE

Until now, researchers have had to spend many hours each week scanning numerous journals and current awareness publications to keep up-to-date with recent developments in their respective fields. Now, with Medical Science Weekly, there is a quick and easy way to keep up-to-date using your own PC.

Medical Science Weekly is best described as a computerised current awareness journal. Each week, you receive a floppy disk with details of the complete contents of over 1000 of the most important biomedical research journals.*

Medical Science Weekly is easy to use. You place the disk in your drive, and, by typing one or two keywords, retrieve all the current articles published in your research field. You can also search for a particular author or reproduce the contents lists of your favourite journals.

Medical Science Weekly is fast. All items from a journal issue are available for distribution within 5 days of receipt at our office.

Receive your weekly update the easy way – at a surprisingly low price! Return the coupon below and we will send you more information and a complete sample system, or call on + 31-6-022-1766 (Europe) 800-HLP-EMED, or (212)-633-3971 (USA and Canada).

COUPON

I would like to receive a Medical Science Weekly sample system (please indicate disk format required)

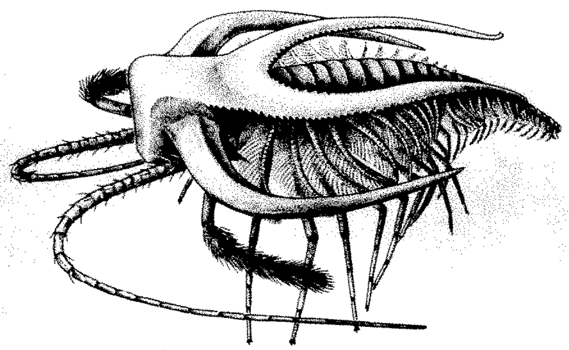
Wonderful Life: The Burgess Shale and the Nature of History. By Stephen Jay Gould. *W. W. Norton: 1989. Pp. 346. $19.95. To be published in Britain by Hutchinson, February 1990.*

THE Burgess Shale, which crops out high in the Rockies of western Canada, is a deposit of mid-Cambrian age. It was discovered in the last century by the great American palaeontologist C.D. Walcott, and preserves an astonishing array of soft-bodied animals which allows us a glimpse of the true range of organisms present at an early stage in metazoan history. In *Wonderful Life* Stephen Jay Gould describes the investigation of this famous fossil fauna: "the world's most important fossil animals".

Gould brings alive the monographs and descriptions of these animals which H.B. Whittington and his colleagues have prepared with such care over the past two decades. He presents the unravelling of the morphology of the remarkable finds as an intense psycho-drama, slapping on a bit of hyperbole here, and a colourful analogy there, to buoy the reader through passages that might seem too technical in any other hands. There is no question about the historical importance of the Burgess Shale, and Gould is right when he says that it deserves a place in the public consciousness along with big bangs and black holes.

But the story is directed to a particular end, and it is this end which, to Gould, lends the Burgess fauna its real interest. His contention is that here we see "a disparity in design far exceeding the modern range throughout the world" (p.62). Organisms from the Burgess Shale may belong to phyla unknown in the living fauna; the arthropods — the most important element in the fauna — do not conform to modern groups, with few but important exceptions. Instead we have a time of wild experiment, with morphological components picked like items from a menu in a Chinese restaurant, and placed together in combinations that no longer exist. The subsequent, post-Cambrian, history of life is seen as one of loss of designs — impoverishment, if you like — in spite of the wondrous variety of the modern world. This is surely a dramatic story, but is it true?

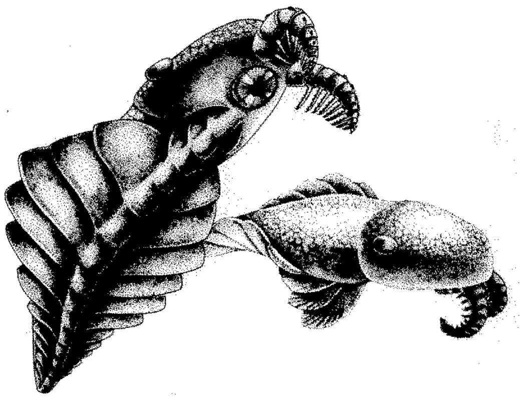


Marella — small and elegant.

Gould follows a traditional line in taxonomic attitude. The taxonomic status (equivalent to importance) of a group is decided by what he terms 'disparity', which means the morphological 'distance' from other groups. A breakthrough occurred, he maintains, when the Burgess arthropods were recognized as including "a series of unique designs, beyond the range of later groups" (p.168). The most peculiar animals of all might be designated as hitherto unknown phyla, the highest taxonomic division below the Kingdom. Curiously, Gould hardly mentions the new discipline of cladistics, which was being developed at exactly the same time as Conway Morris, Briggs and Whittington were patiently chipping out Burgess oddities. The cladistic method works by analysing shared similarities, and produces a classification based on derived, homologous characters; and it does not make value judgements about 'disparity'.

The problem with 'disparity' is that its estimation depends on the authority of the expert: how is he to know what makes — what is 'worth' — a phylum? Or what a class? For the Burgess Shale the answer seems to be lack of success in assigning the taxon into a known, living group, so that the fossil becomes 'an animal with no modern relatives'. But unless the animal arose afresh from the mud it *has* to have some modern relatives, be they ever so distant. The end product of the 'disparity' approach seems to be the insouciant recognition of a new phylum, as if it were only to be expected (on p.143 Gould quotes one prominent researcher as remarking, "Oh fuck, another new phylum", on the discovery of a new form).

For systematic affinities to be discovered, the arthropods from the Burgess Shale *can* and should be analysed in terms of the characters they share rather than those they uniquely possess. They seem to fall into a rather ordered array, with *Marrella*, Walcott's original 'lace crab', as the most primitive member, and the trilobites surprisingly advanced. A similar exercise on echinoderms has seen the positioning of numerous so-called Cambrian 'classes' within a coherent phylogenetic picture. The advantage of this kind of analysis is that it suggests further fruitful questions. For example, the arthropods are metameric organisms, and the characteristic arrangements of appendages (legs, gills and the like) of groups living today may have been assembled piecemeal; the Burgess Shale animals, for all their oddity, may record the stages in this assembly. Hence the fossils may be vital to the understanding of arthropod phylogeny; their apparent 'disparity' may partly reflect the process of assembly of advanced clades.



Anomalocaris — a "capable swimmer".

Scientific discussion will centre on the homology of particular characters, which is always controversial in arthropods. But sorting out such complex questions provides more constructive insights into the classification of these arthropods than simply saying: "Gee isn't that weird — it must be a new class!". One might suspect that if, say, the stalked goose barnacles had been known from the Burgess Shale alone ("an arthropod-like animal covered in calcareous plates and with a flexible stalk — goodness gracious!") they would have found themselves in a new phylum. Yet we know from their development that they are specialized crustaceans. It is about time that organisms were classified by characters they share rather than by intuitions about 'disparity'.

Whatever one makes of their relationships, Gould is surely correct in saying that these animals are among the most important for understanding the history of life. Study of them has demanded patience and persistence, and has mostly been carried out with microscope and pencil and paper rather than the high-technology, high-expenditure approach typical of fashionable science. *Wonderful Life* is a compelling story, told with characteristic verve. □

Richard A. Fortey is in the Department of Palaeontology, British Museum (Natural History), Cromwell Road, London SW7 5BD, UK.

Drawings, by Marianne Collins, are taken from the book reviewed here.

erotic pictures).

Meantime, Sherpa Stafford is slaving away at hush-hush experiments to prove Cantor's cancer theory. These are so hush-hush and *so* exhausting that they drive Celestine to complain about his sexual inadequacies, as she soaps his nether regions, using that four-letter word which Ken Tynan — like Carl Djerassi — did not shrink to use. Eventually, Stafford succeeds and all is set for the vital letter to *Nature* which eventually yields the "Nobel in medicine". But not before a lot of worry and unpleasantness about the inability of Kurt Krauss, I.C.'s nasty competitor at Harvard Medical School, to repeat poor Stafford's work. Had Jerry fiddled the results? We are not really sure even when Celestine is disturbed with another boyfriend — appropriately called Roger — to learn that Jerry is to share the Nobel prize with I.C.

Celestine goes along to Stockholm with her Auntie Paula and they all have a *wonderful* time — pages of it — with both I.C. and Jerry spouting T.S. Eliot in their speeches and Jerry having a nice gossip with the Swedish Queen about how the Brits use their knives and forks and eat peas.

And that's about it really, apart from some reasonably happy endings — all neatly tied up — and a final bitter letter to I.C. from poor old Krauss, who is still as sick as a parrot about not getting his Nobel prize.

What, I wonder, were Professor Djerassi's motives in writing this book? Is he condoning what he portrays? Is he saying, look, this is how it is. What a smart lot we scientists are: pushy, clever, cutting corners (nudge, nudge), getting a bit on the side (snigger, snigger), swanking about our erotic pictures and Boccherini! If he is, then the hell with it. If, on the other hand, he is saying, look, this rat race is awful, then *Cantor's Dilemma* is a clever, if stomach-turning, way of portraying it. □

John Treherne, novelist and scientist, died on 23 September. This rumbustious review was characteristic of the writer and the man.

Ideal thinking

Steven Rose

Russian Psychology: A Critical History. By David Joravsky. *Basil Blackwell: 1989. Pp. 583. £45, $34.95.*

IMAGINE a book entitled *American Psychology: A Critical History,* the first third of which advances that history no further than 1917, the bulk of which follows events only to the early 1930s, and which devotes a mere 30 pages to the years since 1953 – years that have seen such a flowering of the neural and behavioural sciences, and the transformation of our understanding of brain and behaviour. That this disproportion does not seem wholly incongruous for a Western history of Soviet psychology is of course indicative of the extraordinary interest that the first 36 years of the tortured (and torturing) relationship of Soviet communism with science has held for political philosophers, historians and scientists alike. Nor would a history of American psychology of the period (unless of course written by Mr Leo Abse, MP, the recent biographer of Britain's present Prime Minister) be likely to find space for a psychological analysis of F.D. Roosevelt, as this book offers for Stalin. But it also reveals the limits of that interest, for Stalin's death in 1953 is precisely the midway point between October 1917 and the current era, and the second half of this period should surely be as relevant and subject to historical scrutiny as the first for what claims to be, as Joravsky's book does, a comprehensive account.

The superficial view of Soviet science under Stalin sees the period straightforwardly as one in which scientific data and theory were subordinated to political ideology, typified by the Lysenko episode in genetics, often regarded as a simple reciprocal of Nazi eugenics. Such an account misses the passionate concern of Marxism to see itself simultaneously as science and metascience, and the equally powerful determination of an impoverished and backward country to embrace and use science in its desperate push towards modernization. Equally, an unquestioning acceptance of the Western liberal view of science as neutral and above politics, philosophy or ideology misses the opportunity to see, in that Soviet experience, a mirror of some of the problems about the place and organization of science in our own society.

A number of Western scholars have tried to move beyond this simplistic view; the Lysenko affair has been reassessed by Levins and Lewontin, by Lecourt and by Joravsky himself, while Loren Graham's comprehensive *Science and Philosophy in the Soviet Union* has recently been revised and republished. Joravsky's earlier essay in this direction, *Soviet Marxism and Natural Science,* was for a long period after its appearance in 1961 the only book on the theme in English.

The development of Soviet psychology is of particular interest. First, psychology had strong roots in pre-revolutionary Russia, stretching back through Pavlov to Sechenov. Second, the subject matter of psychology has profound bearing on theories of human nature and society, and hence *a fortiori* on Marxism. Third, the theoretical battle between materialism and dualism, between reductionism and dialectics, which in many areas of science is masked or confined to the philosophers, has been and remains a vital issue of methodology and scientific practice for research in psychology and neurobiology in the West as well as the East. Finally, the vast experiment in social engineering in the Soviet Union during the first half of its post-revolutionary history was directed to the creation of "the new socialist man [*sic*]", and one might well have expected that psychologists would find themselves mobilized to this task.

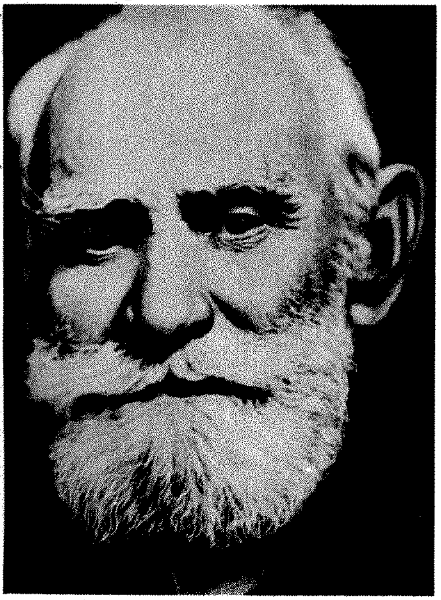
Thus, from the 1920s on, Soviet neurophysiologists, psychologists and philosophers struggled to develop an adequate theory of the dialectic of brain and society in the production of mind, and an adequate practice of pedology (educational science) and psychotechnics based upon that theory. This struggle with some of the deepest conceptual and methodological problems with which science has to cope, produced responses ranging from the hard-line physiological materialism of Pavlov almost until his last days, through the pioneering work on the social production of mind by the polymath Vygotsky and the later development of neuropsychology by Luria. In the next generation it produced Rubinshtein's activity theory, Anokhin's functional systems approach, the work of Beritashvili, Leontiev and Orbeli, as well as a strong school of functional neurochemistry.

And of course, the work of nearly all of these scientists was punctuated by endless crises, from the desperate economic situation and famine of the early years (to be repeated during the 'Great Patriotic War'), through the increasing tendency to solve scientific disputes by administrative fiat – with all the dread consequences that that entailed – from the 1930s to well beyond the death of Stalin. The debates in psychology seem not to have been quite so literally life-and-death affairs as they were in genetics, although Joravsky lists many victims of the Gulag. True, after 1945 Pavlov was for a time elevated to stardom within Stalin's pantheon, and recantation was forced upon those of his pupils and disciples whose greater understanding of brain physiology and psychology (to say nothing of their better Marxism) led them to deviate from the line of their late master. Even so, the debates in the 'Pavlov sessions' for psychologists, physiologists and psychiatrists in 1950, 1951 and 1952 seem much less staged and more open than the notorious 1948 session of the Agricultural Academy which saw the destruction of genetics and the apotheosis of Lysenko.

Just why this should be so would seem to be a question of some significance – perhaps it was because of the stronger research and philosophical traditions of Soviet psychology and physiology;

perhaps because the declared luminary of the subject, Pavlov, unlike Lysenko, was long dead; perhaps because there was a greater urgency to solve the practical crisis in agriculture than to employ science instead of naked coercion in the production of the new socialist man.

Oddly, however, although Joravsky documents the debates extensively he makes no great effort to address these broader questions, and the omission is characteristic of a book which in the last analysis yields much less than it promises. Joravsky is not an internalist historian; he is not so much concerned with experimental findings which led Pavlov, Kornilov, Vygotsky or Luria to their theoretical positions, or with the ebb and flow of the scientific debate; rather, he is offering us a metahistory of psychology, an account of the ways in which the leading protagonists of the discipline in the 1920s and 1930s sought to locate their theories within the swirling currents of the party-led attempts to establish a Marxist orthodoxy. In effect this book is not so much a history of Russian psychology but of psychology in Russia.



Mary Evans Picture Library

Pavlov — developing theories.

The author's scholarship is formidable, and the phrenology he has created whilst denied entry into the Soviet Union or access to many key papers is impressive, despite the fact that the book has, on internal evidence, been a very long time in the making and is the weaker for it. Nonetheless, Joravsky creates the strong impression of being in the last analysis rather bored by the scientific questions which dominate the professional lives of the subjects of his history. A reader of this book who opened it knowing nothing even of Pavlov's key experiments and theories would close it being little the wiser, though he would have learned that Pavlov was a vain, opinionated and authoritarian little man whom Joravsky doesn't like very much. Indeed, Joravsky finds it difficult to observe admirable qualities in almost any of his protagonists. If they don't speculate about the broader significance of their results he finds them narrow technocrats; if they do, they are shallow philosophers, or time-servers who would mould their theories to political exigencies. The treatment — or rather dismissal — of Rubinshtein, Luria and Anokhin in this way is inexcusable in however critical a history. A couple of what Joravsky would probably regard as boringly internalist histories of Russian psychology were published some years ago and do a much more useful job in this regard.

Joravsky would probably respond by saying he wasn't trying to write that sort of book at all. His elegantly worked-over prose, full of ironic asides, musing self-reflections and studied ambiguities may in some ways best be read as an unspoken historiographic debate with what has become known as the Edinburgh school in the sociology, history and philosophy of science, which seeks to reduce debates about fact and theory in science to a reflection of the interests — the social origins and positions — of the main characters. Joravsky's own interest, as the doyen of the history of Soviet science in the West, remains somewhat unstated. He offers himself as an outsider, neither a sympathizer with nor enemy to communism, an olympian observer and chronicler. But in practice he cannot sustain such detachment; his language constantly lets him down, as when, for all his reading of the Marxist classics, confronted with that robust concept 'working class' he routinely bowdlerizes it to 'lower class'. A real critical history of Soviet psychology, which transcends internalist–externalist boundaries, and helps us to rescue its rational kernel from both Eastern and Western ideological trappings, remains to be written. It will be worth waiting for. ☐

Ray Desmond

The Art of Botanical Illustration: The Classic Illustrators and Their Achievements from 1550 to 1900. By Lys de Bray. *Christopher Helm, London: 1989. Pp. 192. £25.*

The drawing of flowers — whether for research, decoration or simply for pleasure — is the subject of an impressive literature. A distinguished pioneer in this field was Agnes Arber, whose survey of printed herbals and their woodcut illustrations, *Herbals: Their Origin and Evolution* (1912; 2nd edn, 1986), has become a classic. Another well-known and authoritative text is Wilfrid Blunt's *The Art of Botanical Illustration* (1950; 3rd edn, 1955). His *Illustrated Herbal* (1980), written in conjunction with Sandra Raphael, complements Arber's volume in dealing primarily with the manuscript herbal.

These are just three of many books dealing with aspects of botanical art that have appeared during the course of this century, many of them during the 1970s and 1980s. Artists such as Leonardo de Vinci, Albrecht Dürer, Jacques le Moyne, Georg Ehret, Sydney Parkinson, Pierre-Joseph Redouté, Mrs Delaney and Marianne North have all been the subject of monographs. Other authors have looked at flower drawing and painting from the point of view of the bibliographer and the printer, while exhibitions, museums and auction houses have each generated accounts of specific collections.

Any new book in this area has to be judged against the high standards set by some of its predecessors. Even though Lys de Bray's *The Art of Botanical Illustration* has no pretensions to original research, aimed as it is at a general readership, and is generously illustrated with colour plates, it is an unhappy piece of work. There are frequent signs of haste in its preparation and the text bristles with errors — misspellings, mistakes in dates of birth and death and in dates of publication — some of which are doubtless due to careless proof reading.

These slips are irritating but others are more misleading. Jacobus van Huysum was employed by Sir Robert (not Horace) Walpole; William Kilburn did not contribute any plates to the *Botanical Magazine*; B. Maund and E.D. Smith were connected with the *Botanic Garden* not the *Botanical Register*; J.N. Fitch lithographed plates for the *Botanical Magazine* but he did not succeed his uncle as artist to the journal. There is no evidence that William Kent landscaped the Prince of Wales's garden at Kew (which was much more than the 11 acres stated by Ms de Bray); Princess Augusta did not extend her property at Kew after the death of Queen Caroline; and W.T. Aiton did not resign from Kew in 1841, he merely relinquished control of the small botanical garden there. This is not an exhaustive list.

It is unfortunate that the author should have chosen *The Art of Botanical Illustration* as her title because it invites comparison with Wilfrid ('Wilfred' in Ms de Bray's book) Blunt's volume. Clearly, though, it poses no threat to the status of the earlier work. ☐

Ray Desmond is at the Royal Botanic Gardens, Kew, Richmond, Surrey TW9 3AB, UK.

NEW FROM OXFORD

AUTUMN BOOKS

The Emperor's New Mind

Concerning Computers, Minds, and the Laws of Physics

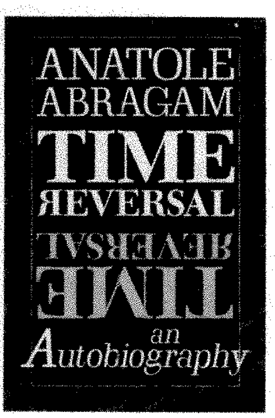
Roger Penrose

This intriguing book, by brilliant theoretician Roger Penrose, puts forward his view that there are some facets of human thinking that can never be emulated by a computer.

'It is a book that I believe will become a classic.' **Martin Gardner**

0 19 851973 7, 480 pp., illus., 1989 £20.00

© The British Council 1989



Time Reversal

An Autobiography

Anatole Abragam

The distinguished physicist gives a candid description of his life, times, and colleagues, replete with anecdotes and illuminating pen-portraits.

0 19 853926 6, 382 pp., illus., Clarendon Press, 1989 £25.00

The Solid State

From Superconductors to Superalloys

André Guinier and Rémi Jullien

Provides the non-specialist with a clear introduction to the solid state, and looks at the technological importance of some of the recent advances in this field.

International Union of Crystallography Texts on Crystallography No. 1

0 19 855290 4, 288 pp., illus., 1989 £40.00
0 19 855554 7, paperback £15.00

Journey into Light

Life and Science of C. V. Raman

G. Venkataraman

While Raman's work is famous, the man himself was often misunderstood and maligned. This biography offers a lively account of the life of a colourful personality, and sets it in its social and cultural context.

'A model of scientific biography . . .' **Nature**

81 85324 00 X, 578 pp., illus., OUP/Indian Academy of Sciences in co-operation with Indian National Science Academy, 1989 £22.50

NEW EDITION

Free Radicals in Biology and Medicine

Second Edition

Barry Halliwell and John M. C. Gutteridge

The explosive growth of interest in free radicals in recent years has created the need for this edition. The text has been extensively rewritten and the references updated to include recent research.

0 19 855294 7, 544 pp., illus., Clarendon Press, 1989 £50.00
0 19 855291 2, paperback £22.50

Modern NMR Spectroscopy: A Workbook of Chemical Problems

Jeremy K. M. Sanders, Edwin C. Constable, and Brian K. Hunter

One of the important skills that a practical chemist needs is the ability to interpret NMR spectra. The aim of this workbook is to develop that skill to an advanced level. It achieves this by a combination of worked examples and set problems that cover one- and two-dimensional techniques applied to organic and inorganic systems.

0 19 855287 4, 128 pp., illus., paperback, 1989 £9.95

Lasers and Mass Spectrometry

Edited by **David M. Lubman**

This volume focuses on the fundamentals of the technique of analysing material based on the atomic weight of the species, using the power and definition of lasers to enable measurement of smaller quantities and more finely localized particles.

Oxford Series on Optical Sciences

0 19 505929 8, 496 pp., illus., OUP USA, October 1989 £55.00

A Dictionary of Concepts in NMR

S. W. Homans

This dictionary is the first to provide a comprehensive explanation of the acronyms and technical terms which have crept into the NMR literature in recent years

Biophysical Techniques Series No. 1

0 19 855274 2, 352 pp., illus., Clarendon Press, November 1989
£40.00

The Chromophyte Algae: Problems and Perspectives

J. C. Green, B. S. C. Leadbeater and W. L. Diver

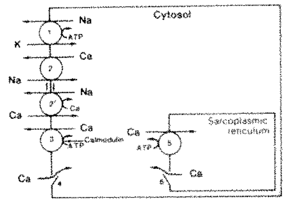
International contributors review the current status of the *Chromophyta*, with particular attention to the ultrastructure, biochemistry, physiology, systematics, and phylogeny of this diverse group of organisms.

Systematics Association Special Volumes No. 38

0 19 857713 3, 432 pp., illus., Clarendon Press, November 1989
£60.00

Sodium–Calcium Exchange

Edited by **T. Jeff A. Allen, Denis Noble, and Harald Reuter**



The way a cell maintains its total calcium content is a central issue in physiology. This book introduces the reader to the role of sodium–calcium exchange in calcium homeostasis.

0 19 854735 8, 344 pp., illus., 1989 £40.00

Molecular and Genetic Aspects of Nitrate Assimilation

Edited by **John Wray and James Kinghorn**

Efficient nitrate metabolism is vital for healthy plant growth. This book discusses current studies on the genetics and molecular biology of nitrate uptake, reduction, and regulation, and identifies research priorities for the future.

0 19 857696 X, 432 pp., illus., November 1989 £45.00

The Neurobiology of Memory

Concepts, Findings, Trends

Yadin Dudai

What changes take place in molecules and nerve cells in our brain, when we learn and remember? How many memory systems do we have, and how are they affected by disease? Drawing from several fields of modern neurobiological research, this book describes and explains the state-of-the-art answers to the above and many other questions concerning learning and memory.

0 19 854261 5, 352 pp., illus., 1989 £40.00
0 19 854229 1, paperback, 1989 £18.00

Human Origins

Edited by **John R. Durant**

Leading archaeologists, anthropologists, biologists, and palaeontologists here present a vivid portrait of what we know about the evolution of our species. Contributors include Richard Dawkins, Alec Jeffreys, and Richard Leakey.

0 19 857612 9, 158 pp., illus., Clarendon Press, 1989 £25.00

OXFORD UNIVERSITY PRESS

Autumn Releases from Springer-Verlag

J. D. Lambris, Basle (Ed.)

The Third Component of Complement

Chemistry and Biology

1989. Approx. 270 pp. 38 figs. 18 tabs. (Current Topics in Microbiology and Immunology, Vol. 153)
Hardcover DM 148,- ISBN 3-540-51513-5

The papers assembled in this volume bring the reader to the forefront of research on the third component of complement, one of the most versatile and multifunctional molecules known to date.

D. Schlossberg, Temple University, Philadelphia, PA (Ed.)

Infectious Mononucleosis

2nd ed. 1989. XIV, 203 pp. 39 figs. (Clinical Topics in Infectious Disease) Hardcover DM 158,- ISBN 3-540-96959-4

Thoroughly revised and expanded, this comprehensive reference details all aspects of infectious mononucleosis, discussing the etiology, epidemiology, and pathogenesis.

Monographs on Endocrinology

Volume 31
F. A. Kincl, City University of New York, Staten Island, NY

Hormone Toxicity in the Newborn

1990. Approx. 368 pp. 27 figs. Hardcover DM 268,-
ISBN 3-540-51153-9

This monograph surveys the teratological effects of hormones in the neonate and in the fetus, bringing together all such information in one volume for the first time.

Volume 32
J. W. Everett, Duke University, Durham, NC

Neurobiology of Reproduction in the Female Rat

A Fifty-Year Perspective

1989. X, 133 pp. 73 figs. 37 tabs. Hardcover DM 178,-
ISBN 3-540-51157-1

This volume, written by one of the pioneers of neuroendocrinology, gives a concise, running account of investigations which have contributed fundamentally to present understanding of regulatory processes in the female reproductive cycle.

Prices are subject to change without notice.

Reviews of Physiology, Biochemistry and Pharmacology

Volume 113

1990. VI, 154 pp. 12 figs. 5 tabs. Hardcover DM 104,-
ISBN 3-540-50948-8

Contents: *A. Kurtz:* Cellular Control of Renin Secretion. - *U. Walter:* Physiological Role of cGMP and cGMP-Dependent Protein Kinase in the Cardiovascular System. - *E. Ozawa:* Transferrin as a Muscle Trophic Factor.

Volume 114

1990. VI, 260 pp. 21 figs. 9 tabs. Hardcover DM 148,-
ISBN 3-540-51693-X

Contents: *H. Glossmann, J. Striessnig:* Molecular Properties of Calcium Channel. - *D. Pelzer, S. Pelzer, T. F. McDonald:* Properties and Regulation of Calcium Channels in Muscle Cells. - *H. Porzig:* Pharmacological Modulation of Voltage-Dependent Calcium Channels in Intact Cells.

F. Ginsberg-Fellner, New York, NY; **R. C. McEvoy**, City University of New York, NY (Eds.)

Autoimmunity and the Pathogenesis of Diabetes

1990. Approx. 288 pp. 71 figs. (Endocrinology and Metabolism: Progress in Research and Clinical Practice, Vol. 4)
Hardcover DM 168,- ISBN 3-540-96645-5

This text offers a balanced overview of the several lines of evidence suggesting that in genetically susceptible individuals, classic Type I diabetes mellitus results from autoimmune destruction of the pancreatic beta cells.

A. Habenicht, University of Heidelberg (Ed.)

Growth Factors, Differentiation Factors, and Cytokines

1989. Approx. 480 pp. 60 figs. 54 tabs. Hardcover DM 198,-
ISBN 3-540-51322-1

Leading international experts contribute to this selection of reviews covering the merging fields of growth factors, differentiation factors, and cytokines, providing an important update in this pioneering field.

M. Steriade, D. Paré, B. Hu, M. Deschênes

The Visual Thalamocortical System and Its Modulation by the Brain Stem Core

1990. Approx. 175 pp. 27 figs. (Progress in Sensory Physiology, Vol. 10) Hardcover DM 124,- ISBN 3-540-51380-9

This monographic work authored by eminent neurophysiologists will be of major interest to researchers investigating the visual system or working in behavioral neuroscience and sleep research.

Adventures of Ben Trovato

Walter Gratzer

Discovering: Inventing and Solving Problems at the Frontiers of Scientific Knowledge. By Robert Root-Bernstein. *Harvard University Press: 1989. Pp. 501. $35. To be published in Britain next month, £27.95.*
Fortune or Failure: Missed Opportunities and Chance Discoveries in Science. By Alexander Kohn. *Basil Blackwell: 1989. Pp. 199. £14.95, $24.95.*
Serendipity: Accidental Discoveries in Science. By Royston M. Roberts. *Wiley: 1989. Pp. 270. Hbk $19.95, £13.30; pbk $12.95, £8.65.*
Harrap's Book of Scientific Anecdotes. By Adrian Berry. *Harrap, London: 1989. Pp. 240. £12.95.*

MURPHY's law, or as the French call it, *le loi d'emmerdement maximum,* dictates that when we drop the breakfast toast on the newspaper or floor it always falls spread-side down. Imagine now recovering the errant morsel and finding, when you turn it over to scrape away the bits of carpet, the long-lost contact lens embedded in the marmalade. This, according to Royston Roberts, is serendipity. Consider next the case of the American professor of statistics, who observed that when his children dropped their bread and butter on the carpet it always landed buttered-side up. A violation of Murphy's law? By no means, for on looking into the matter more closely the professor found that his children were buttering their bread on both sides. This Dr Roberts calls pseudo-serendipity — an unsought discovery that comes to reward the deserving, those whose minds are equipped to receive and interpret the signal, who descry that tide in the affairs of men, which taken at the flood leads on to fortune.

Should you feel impelled to buy these four books, you will learn, not once but four times, that serendipity is a coinage of Hugh Walpole's, derived from the Persian fable of *The Three Princes of Serendip* (that is to say Ceylon, or if you prefer, Sri Lanka), meaning the happy faculty of making unexpected and fortunate discoveries. Robert Root-Bernstein explores the phenomenon in the greatest depth and his is by far the most ambitious work. It is cast in the form of a running seminar, for six voices, about the nature of the scientific process. One of these, referred to as Imp, I take to be the author's *alter ego.* The discussion ranges over the practice, philosophy, organization and sociology of science with no little erudition, even if one occasionally fancies that one is being beaten about the cranium with it ("As Paul Valéry says . . ."). Imp and his friends develop many a provocative but abundantly documented thesis. Science, they find, for example, is getting worse: ever more scientists are generating less and less new knowledge per head; the success of science at the national level does not reflect the munificence of its funding. Many small countries — Denmark is one — do better than the United States, let alone the Soviet Union, by such criteria as Nobel prizes per head of population.

Root-Bernstein's protagonists argue a great deal about creativity. How may it be promoted and can it be taught? The uneasy outcome seems to be that it can be inculcated by educational precept, according to such formulae as used to be advertised by Edward de Bono; the existence of the great scientific dynasties — Nobel laureates begetting Nobel laureates — suggests, on the other hand, that it is better learned by example, as part of the patrimony of a great laboratory.

Contemporary mistrust of Jenner's theory.

Mary Evans Picture Library

Root-Bernstein illustrates his argument with many examples. He favours research by bold and hazardous flights of the intellect: to be audaciously wrong is better than to be timidly correct. ("This theory isn't right", Debye was supposed once to have declared after a seminar, "it isn't even wrong".) Imp is ever keen to challenge the wisdom of the day. Crick's Central Dogma is his favourite target. But here the urbane mask suddenly slips, revealing, as it seems, a bloodshot glint of messianic fire; for it is Root-Bernstein's own work (published in the *Journal of Theoretical Biology*) that his surrogate cites in evidence. He is out to black the Establishment's eye by breaching the infamous Central Dogma with a demonstration that information can flow from protein to protein. Model building leads him to a scheme of complementary amino acids. In search apparently of a spot of serendipity, he meanders down a byway and arrives at a model for an interaction between a neurotransmitter, serotonin, and myelin basic protein. Imp speaks highly of Root-Bernstein's work. He then goes on to denounce the intolerance of the guardians of entrenched opinion towards such enterprising conceits as four-stranded DNA structures, and the purblind reluctance of grant committees to shell out money for the pursuit of heterodoxy. I find this slightly queasy reading: it seems to me to come close to the cry of the crackpot down the ages, demanding a blank cheque to support what Irving Langmuir called (with criteria by which it could be recognized) pathological science.

Root-Bernstein quotes with approval Albert Szent-Györgyi's remark about the fatuity of a system of funding that required of him some indication of what he proposed to do with the money. If, he maintained, he knew what he was going to discover, there would be no need for him to discover it. Judged by this argument of course all discoveries are by their nature serendipitous. But Root-Bernstein goes on to make a compelling case that the grant system is becoming increasingly rigid, and acts to discourage those digressions in pursuit of the unexpected that have so often led to the most striking discoveries. His analysis of conceptual upheavals in science over the past century or so also leads him to the conclusion that a large proportion have come from unknown researchers, operating alone in the geographical wilderness. If he is right then the cultivation of 'centres of excellence' and the projected elimination of research from minor seats of learning in Britain are a dangerous folly. Our scientific mandarins should examine his evidence with care.

Another of the contentions ventilated by Imp and his companions is that the creative process is nourished by artistic imagination, and that the scientific elect most often possess accomplishments in music, in painting or in poetry. The evidence is marshalled in a table that spreads itself over several pages. This may be right, but for my part I have too often found the giants of our profession to be boorish thugs to be wholly convinced. Moreover, while there may be no doubt about Einstein's love of music, his proficiency on the fiddle by all accounts did not far outstrip that of Heifetz in cosmology. (His frequent partner, Martinu, who wrote a sonatina for him, was supposed to have snapped in exasperation: "Damn it, Einstein, can't you count?")

But enough grousing, for Root-Bernstein has written an absorbing, stimulating, sometimes infuriating book, full of entertaining ideas, and everyone with an interest in science and its ways will benefit from reading it. ▶

Alexander Kohn and Royston Roberts plough the selfsame furrow. All the old tales are here, nor do they fade with the telling, and there are also a good many I did not know. Both miss the story of Dr Murphy's patient in Boston, who was fond of raw liver and became cured of pernicious anaemia, but not much else that I could think of. Kohn concentrates more on medical discovery, and in today's world of mandatory LD50 tests, clinical trials and FDA approval, the casual manner in which dire procedures were tried on human subjects — the family, often enough, of the experimenter — taxes credulity. Jenner, it may be remembered, "with great fortitude tried the cow-pox on his wife and children", but before that he had taken the precaution of inoculating a farm-boy, James Phipps, and then injecting him with the real article — a smallpox extract. Much more recently a research director at Boehringer, screening a series of compounds for vasoconstrictor activity to use against the common cold, tried one out on his snuffling secretary; she promptly sank into a sleep that lasted 24 hours, and her blood-pressure was found to be alarmingly low. By this means clonidine, the sovereign treatment for hypertension, was discovered.

In Memoriam

For "quaker", pray, and for "moth-eaten", mourn.
This threnody recalls their fate forlorn.

We catered to their reproductive need.
We cherished and encouraged them to breed.
We nourished them (for 15 cents a day)
Until, on orders, they were shipped away:
Their natures chromosomally imbued
With genes for "non-immunity" or "nude",
From whites to pure C-57 blacks:
A thousand, thousand cultivated JAX.

In two score years and two, that realm of mice,
Felled once by fire, has now been stricken twice,
Ignited by explosion of propane
To holocaust in far Bar Harbor, Maine,
Where, cage on cage, in box on burning box,
There perished scores of rare foundation stocks.
On shelf and bench, in closely serried racks,
There died a pyre of martyred murine JAX.

Weep, then, for mice in Roscoe Jackson's name,
Incinerated in a burst of flame.
Like fair Brunhild', by fiery circle girt,
They died, the noblest breeds of Mount Desert.
Their bodies ashed, their genes distilled away—

Mourn for "moth-eaten", and for "quaker", pray!

Ralph A. Lewin

In the drug field, especially, the exercise of reason seems to have played little part in the best discoveries. Lithium therapy is an example to make any rational pharmacologist put by his smoked drum and seek a tranquil retirement. Kohn tells the story well: an Australian psychiatrist conceived the notion that manic disease was caused by a toxin, and that this would appear in the urine. So he injected the urine of his patients into guinea pigs. The guinea pigs reacted badly, but less so, he judged, to control urine. The next stop was to identify the toxic principle. Urea killed the guinea pigs, but its concentration was the same in manic and normal urine. How about uric acid then? But free uric acid is insoluble, so the dauntless experimenter prepared the lithium salt. Not only did it appear innocuous, but it counteracted the toxicity of urea and exerted a 'calming effect' on the agitated rodents. To do the psychiatrist justice, he did then ask himself whether it was the uric acid or the lithium that was exerting the benign affect, and indeed lithium carbonate proved equally soothing. He now tried lithium carbonate on a patient, with miraculous results. A paper was written and ignored until it was discovered in the fringe literature by a Danish worker some years later. Lithium therapy became in due time one of the great triumphs of clinical science; but manic patients have no toxin in their urine and the guinea pigs became quiet only because the lithium made them sick.

Roberts is an organic chemist and his trade is perhaps the richest of all in fortuitous and perverse discoveries. He has written an entertaining book, accessible to all. Here is Dr Sapper, who breaks a thermometer in the reaction vessel and is rewarded by the discovery that mercuric ion is a catalyst for the oxidation of naphthalene to phthalic anhydride, and so begets the modern dyestuff industry. Roy Plunket, in search of a better refrigerant, sets out to try a prep with tetrafluoroethylene. The weight of the gas cylinder shows it to be full, but nothing comes out. On being sawn open it yields up a waxy solid, now known as Teflon. A negligent graduate student leaves his cigarette smouldering on the bench while he works; he takes a drag and finds that it tastes intensely sweet. He has discovered saccharine. Forty years later James Schlatter at Searle, pursuing ulcer drugs, is synthesizing a terminal dipeptide of gastrin. He licks his fingers and experiences a sensation of sweetness. He tastes his dipeptide ("It was a bold man who first swallowed an oyster", said King James), and lo, aspartame or Nutrasweet is the fat man's friend. And so it goes.

Who are these holy innocents, whose curls fortune ruffles with her fingers, while giving the rest of us the flat of the hand across the windpipe with the other arm? Roberts believes they are just like us, only quicker of wit and sharper of perception. For every one of them there must be a thousand others, who failed to take the tide at the flood, and the voyage of whose lives was accordingly bound in shallows and in miseries.

Kohn enlarges on the subject of missed opportunities. These tales are inevitably harder to come by, but he tells for example of a well-known biochemist, still among us, who went to the wrong seminar and failed to initiate a collaboration which would probably have started recombinant DNA a year or two early. He might have mentioned also the Japanese physicist, who shelved an observation that should have led him to the discovery of the neutron; it was said that in his later years cruel students would drop the word in his presence to see the tears well up and course down his cheeks. But what of all the discoveries and inventions that have not been made? Like children unconceived, they will never be missed, but one can imagine them massing in the shadows to mock the bureaucrats who work so hard at keeping scientists away from the paths of dalliance.

On his deathbed, Lord Camrose was supposed to have addressed the following exhortation to his assembled family: "If you want to die as rich as I am, never brighten up *The Daily Telegraph*". But do not let this put you off *Harrap's Book of Scientific Anecdotes,* which comes from the pen of the *Telegraph*'s science correspondent. The book is not what its title suggests, but rather a collection of Adrian Berry's favourite passages of scientific and technological journalism, yarns of discovery and exploration from *The New Atlantis* to Chernobyl. It is agreeably written, spiced with witticisms and altogether good fun.

I shall leave you with just one example of Berry's historical research. It concerns the reception given to Alexander Graham Bell's telephone. The mayor of an American city grasped its potential at once: "One day", he said, "there'll be one in every city". But what did the experts think? Here is the Chief Engineer of the British Post Office, reporting with considered wisdom to a House of Commons committee: "Americans have need of the telephone — but we do not. We have plenty of messenger boys". So much for peer review. □

Sunk without a trace

June Goodfield

The Mind Has No Sex? Women in the Origins of Modern Science. By Londa Schiebinger. *Harvard University Press: 1989. Pp.355. $29.50, £23.50.*

"LET us now praise famous men, and our fathers that begat us", runs the verse from Ecclesiasticus. Not, you notice, that women or mothers were in any way involved nor were they likely to have been present in the writer's mind even as he concluded: "And some there be which have no memorial. Who are buried as though they had never been". It was ever thus, I concluded, as I finished Londa Schiebinger's remarkable book.

Its title comes from an assertion made over 300 years ago by François Pollain de la Barre, as part of an attempt to secure a place for women in the then emerging modern science. The author of this book adds a question mark to his phrase — not because she has any doubts about the matter but, I believe, because over the centuries thousands have stated equally assertively that the fairer sex is also the weaker, both mentally as well as physically. And they have appealed to a whole range of rationales — themselves socially and culturally determined, subject equally to the whims of fashion or assumption — to underpin their preferred judgements. By now no one, I trust, denies that during history women have been largely excluded from scientific institutions (as indeed they have from almost all other institutions) and the mechanisms of exclusion, whether structural, sexual or derived from supposed gender differences, are still largely in operation. Schiebinger's intention is not to add to the burgeoning literature on this topic but to try to understand what these gender differences are, and how they operate in science today. Her chosen method is to examine the past — the revolution in European science in the seventeenth and eighteenth centuries to be precise — in order to answer this problem: what role did the "women question" and the debate over "female nature" play in the origins of modern science?

This is a formidable task, but it has been undertaken by someone of formidable scholarship who is blessed with one additional gift: she understands that social and historical dynamics are highly complex yet has remained undaunted. Halfdan Mahler, when Director General of the World Health Organization, commented recently that "development is a very messy affair" and added "God protect me from the simplifiers". The point applies to this issue too. If we are to make any progress at all in understanding the present inequities, let alone rectify them, we need to eschew simplicity and generalizations and do full justice to the underlying human complexity.

Accordingly, the author approaches her analysis from four different angles but always with the question of gender to the forefront — that is, are men and women different by nature or by nurture; if so, what difference does (and did) this difference make? She explores in turn, first, the institutions of science which in the period under discussion were fostered in a variety of settings (academies, Parisian salons, princely courts and craftsmen's workshops); second, the lives of some women, predominantly from the aristocracy and the crafts, who pressed against the boundaries of convention to practise science; third, how the biological sciences traditionally merged sex (a matter of genes) with gender (a matter of culture, education and expectations) to produce supposedly scientific readings about the female nature that were used equally by those who argued for, or against, women's full participation in science. Finally, her gaze is directed towards the cultural meanings of femininity and masculinity, and how a woman's ability to do science has seemingly become irreparably meshed into issues of gender.

Mary Evans Picture Library

Labour pains — midwives became auxiliaries in a male-dominated medical system.

No one of these elements is, she rightly insists, a causal agent that alone determines where women are in science today. Each, however, had a part in the process, and in the dynamic that determined the present outcome they have all played important and interdependent roles.

The extent of research and the material uncovered is remarkable. Where and how did Schiebinger find it all? For this is intellectual archaeology at its very best, and a landscape is laid out for us the existence of which most readers will be totally ignorant. There are some surprises along the way: matters were not totally ever thus.

Although the extent of women's activity, success and penetration into science varied from class to class and country to country, their ultimate exclusion was not a foregone conclusion. Aristocratic women dominated the discussions in the salons of seventeenth-century Paris; women artesans did notable astronomical and agricultural research in Germany; the Enlightenment was a great time to be alive, when women's desire to be involved in science was assisted by many social trends and even the bastions of some of the new scientific academies were temporarily breached. Yet time after time all such efforts were stymied and it is ironic that the ultimate *coup de grâce* was to come from the very enterprise that women tried to develop. For modern science, too, finally came to codify a view of women that set the seal on their exclusion.

But there is, of course, more than one way to skin a cat, as the history of midwives illustrates. Since ancient times this 'craft' group had peacefully co-existed alongside medical men, each with their own art and monopoly. But both the peace and monopoly were to be shattered in the two centuries in question. Whereas doctors, surgeons, apothecaries, dentists and veterinarians gradually transformed themselves into self-governing, self-regulating professions, midwives never succeeded in doing this though they certainly tried. But still they remained regulated by men — by the King's chief barber–surgeon in Paris, by the clerics in England. Finally, the *accoucheur* appeared — the man-midwife who was now called in for routine cases, not just abnormal labours. By the end of the eighteenth century, midwives were just auxiliaries to a male-dominated medical system: the practice of obstetrics and gynaecology passed over to men.

This example is telling for it illustrates the nature of one of the Catch-22 traps that ensnared so many women who wished to progress in science. Midwives could not learn new methods or practices because they could neither attend universities nor establish their own medical colleges; they could not do those things simply because they were women. No matter what arguments they employed, what authorities they quoted — from the Bible to the new ethnology — to try to secure their ancient privileges, it was hopeless. And when finally they were driven to the argument of 'natural propriety' matters were made even worse. For 'natural innateness' was the final appeal that, above all, kept the women at the hearth in their traditional child-bearing roles.

In giving this account of the role of science in the creation of gender, backed by this mass of fascinating detail, intriguingly interpreted, Schiebinger has truly travelled uncharted territory. But has she really answered her own question? Societies "intent on preserving the sharp social and intellectual distinctions between the sexes" have, for the most part, deliberately cultivated perceived sexual differences. But what are these? Do they indeed exist; if so, what difference does the difference make?

Here these questions are posed rather than answered. Unravelling the multifarious strands of women's role in the history of modern science is an essential first step, brilliantly executed in this book. It is to be hoped that this study will provoke further analysis into the contemporary scene and present powerful trends in science. For every Maxine Singer, now President of the Carnegie Institution of Washington, there are still hundreds of others striving to make their mark in the scientific enterprise in conditions where Catch-22 traps still operate. Will it be ever thus? Sometimes I'm optimistic, but reading what happened in history, and not yet discerning overpowering new trends, sometimes I wonder whether such optimism is justified. ☐

Asking questions

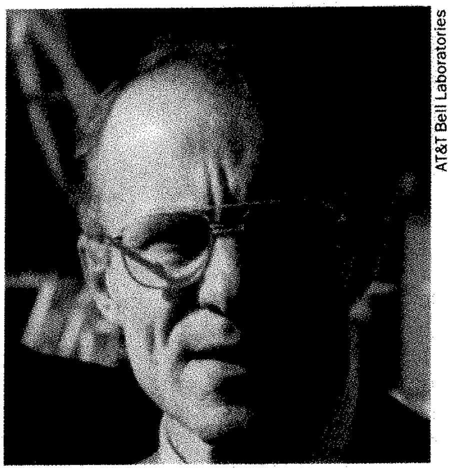
Igor Aleksander

Ideas and Information: Managing in a High-tech World. By Arno Penzias. *W.W. Norton: 1989. Pp. 224. $17.95, £12.95.*

For many people, phrases such as 'the information age' or 'high-tech world' evoke feelings of the hackneyed, the oversold. Not so for Arno Penzias, who sees 'managing in a high-tech world' as a matter of exciting discovery and wonderment. In *Ideas and Information*, Penzias, a Nobel laureate for physics in 1979, glances over his own specialist fence at the nature of information technology and the effects it has had on him and the world he inhabits. The world 'managing' in the subtitle is used in the sense of 'coping': Penzias is a technology enthusiast. His book is intended to give heart to those who feel that coping in a world of faxes, electronic mail, word processing, databases and the like is getting beyond them.

The style is anecdotal without being trivial, authoritative without being overpowering. And it *has* to be enthusiastic because, after all, Penzias is the vice-president for research of one of the world's most renowned information-technology companies: AT&T's Bell Telephone Laboratories. The anecdotes add fun and a personal touch to what could so easily otherwise have been yet another dull catalogue of the benefits bestowed on mankind by the advent of computers. Penzias also goes to great lengths to distinguish the rule-enslaved computer from the free-learning, exploration-loving human being. I suppose that there are still those who get the two confused to the extent that such descriptions are necessary.

The book is written with an implied sense of history: the history of symbols, the history of mathematics and the history of computing machines. Penzias argues that the manipulation of symbols distinguishes computers from other machines in the way that being able to use symbols distinguishes human beings from animals. Symbols were valued by the prehistoric painters of the images in the Lascaux caves in France, by the Sumerians of 3300 BC who invented information storage (tokens in a clay jar), and by the Egyptians and the Chinese, who raised application of their intelligence to higher planes by inventing numbers and mathematics. So, for Penzias, the computer is the ultimate celebration of human intelligence: a machine that embodies the finest points of the use of symbols and manipulations.



AT&T Bell Laboratories

Arno Penzias — "cheerful optimism".

He does not confuse person and machine, however, as seen in this almost thrown-away footnote: "As we explore the computer's ability to match human information-processing capabilities, we shouldn't overlook the fact that these machines have much to offer society without emulating humans". At the same time as he creates the distinction between living and mechanical information processors, he pinpoints the very factor which, if mechanized, could reduce this crucial distance: "On the other hand, I am sure that this situation will change drastically when (and if) we can devise a computing architecture that learns from examples, the way humans do, rather than merely obeying instructions. Nature produces countless billions of such computers in the brains of living creatures". In these sentences he has identified (perhaps unwittingly) the scent that the contemporary hounds of neural-network research have sniffed out, and that is leading them towards learning computers with which they will try to revolutionize computing by narrowing the gap between the mechanical and the biological.

The mix of anecdote, history and insightful comment is a characteristic of the book as a whole. Penzias describes milestones in the making of information machines such as Chomsky's analysis of language, Hopfield's revival of neural nets and Joseph Weizenbaum's totally mechanical 'psychiatrist emulator', Eliza, which makes its interlocutors think that it 'understands' their problems, while it is simply throwing their own words, modified by a few simple rules, back at them.

For me, a high point is reached in Penzias's recounting of I.I. Rabi's description of the reasons for his (Rabi's) success, also crowned by the Nobel prize in physics. "Have you asked any good questions today?", his mother would ask him on his return from school. This, surely, rather than just the ability to learn, must be the factor that best distinguishes organisms that possess intelligence from those that do not. The ones that do ask very good questions.

There are some unfortunate blemishes. Bell Labs is presented as the source of all discovery, which will irritate readers who happen to know that not all high-tech inventions were made at that institution. For example, the comment "At Bell Labs . . . a robotics research group has built a robot that can follow spoken instructions" is followed by a description of work that was done by Terry Winograd at the Massachusetts Institute of Technology in the early 1970s. There is no mention of Winograd. Even Hopfield is described as a Bell Labs' physicist, giving no credit to the fact that he is also an academic at Caltech.

But perhaps the worst sin is that there is no mention of the down side of computers: the overrating of technology for its own sake; the fact that the purchase of information technology in a badly managed organization can amplify the bad management; the need to change one's behaviour to meet the needs of computer-driven procedures (as in banks); new opportunities for fraud; the possibility that people may be forced to become less skilled as well as more skilled. For Penzias these difficulties do not exist, or if they do he may have decided to ignore them for fear of damaging the up-beat tempo of his book. Without a doubt those who need reassurance about coping in the information age will be rewarded by the cheerful optimism purveyed in *Ideas and Information*. Why spoil it with bad news? ☐

///VSP/// BOOKS FROM VSP

MULTIPHASE BIOMEDICAL MATERIALS

Editors: T. Tsuruta and A. Nakajima

This book contains the results of the research project in an edited form and aims to provoke a better understanding about various aspects of cell-material interactions in which the multiphase systems play a crucial role. The following topics are covered: Multiphase biomedical materials with microdomain structures; Multiphase biomedical materials containing liquid components; Hybrid-type multiphase biomedical materials with biological components; Inorganic and metallic multiphase biomedical materials; Methods for analysis and evaluation of multiphase biomedical materials.

1989; viii+194 pages *ISBN 90-6764-109-X*
Price: DM 186/US$ 110

HIGHLIGHTS OF MODERN BIOCHEMISTRY

Editors: A. Kotyk, J. Skoda, V. Paces and V. Kostka

These Proceedings contain the papers from leading experts which were presented during the 14th International Congress of Biochemistry. The contributions are published in two volumes and present the gigantic advances and new trends in all fields of biochemistry and give an idea of new developments in these fields.

1989; Volume 1: xiv+962 pages/Volume 2: xii+834 pages *ISBN 90-6764-117-0*
Price: DM 708/US$ 417

REACTIVE OLIGOMERS

S.G. Entelis, V.V. Evreinov and A.I. Kuzaev

This volume in the series NEW CONCEPTS IN POLYMER SCIENCE gives a systematic presentation of the problem of Reactive Oligomer (RO) molecular heterogeneity from the synthesis theory and practice of analysis to the use of quantitative characteristics of oligomers in producing the corresponding polymers.

1989; xii+322 pages *ISBN 90-6764-107-3*
Price DM 243/US$ 143

POLYMER COMPOSITES

R.B. Seymour

This volume in the book series NEW CONCEPTS IN POLYMER SCIENCE describes the present state of the art of compounding of polymers. In addition to a brief history of composites this book includes chapters on nonfillers such as stabilizers, plasticizers, catalysts, coupling agents and nucleating agents as well as chapters on fillers and fibrous reinforcements. Foams, blends, elastomers and high performance polymers are also discussed as well as general purpose plastics.

1990; xiii+194 pages *ISBN 90-6764-121-9*
Price DM 158/US$ 93

HIGH TEMPERATURE DUST LADEN JETS IN PLASMA TECHNOLOGY

Editors: O.P. Solonenko and A.I. Fedorchenko

These Proceedings contain the papers that were presented during the International Workshop held in Novosibirsk, 6-8 September 1988. The scope incorporates the following aspects: Modelling of the processes of interphase momentum, heat and mass transfer in dust-laden jets as well as interaction between the particles which are in an complex aggregation state; Diagnostics of the parameters of gas and disperse phases in high-temperature dust-laden flows; Processes of the formation of plasma sprayed coatings; Processes of treatment and production of powder materials.

1990; xii+572 pages *ISBN 90-6764-120-0*
Price: DM 323/US$ 190

Progress in Alcohol Research - volume 2 ALCOHOL AND BEHAVIOR

Editors: H. Ollat, S. Parvez and H. Parvez

This second volume in the book series PROGRESS IN ALCOHOL RESEARCH which focuses on the behavioural, clinical and pharmacological research on alcohol includes chapters on: Genetic markers of alcoholism risk; Depression; Effects of alcohol on performance tests; New data on the neuropharmacology of alcoholism; Pharmacotherapy and therapeutic drug trials in alcoholism.

1990; c. 310 pages *ISBN 90-6764-124-3*
Price: DM 200/US$ 118

ESSENTIAL READING FROM CHAPMAN AND HALL

The Dicynodonts

A study in palaeobiology

Gillian King, *University Museum, Oxford, UK*

The Dicynodonts, an important group of Permo-Triassic reptiles, were the first really successful herbivorous tetrapods and left an abundant fossil record. In *The Dicynodonts* a recognized expert in the field summarizes the studies of this significant group of reptiles.

December 1989 246pp, 58 illus Hardback 0-412-33080-6 £35.00

Ecology of Teleost Fishes

R J Wootton, *Department of Biology, University College of Wales, Aberystwyth, UK*

Wootton, who is well known in this field, presents an integrated approach to the subject. Using recent information concerning important theoretical advances in the area the author describes and analyses field and experimental studies of the ecology of a wide range of important fish species.

Fish and Fisheries Series

November 1989 416pp, 143 illus Hardback 0-412-31720-6 c.£39.50
Paperback 0-412-31730-3 c.£19.95

Isozymes in Plant Biology

Edited by **Douglas E Soltis** and **Pamela S Soltis,**
Washington State University, USA

Isozymes, discovered in 1957 by Hunter and Markert, have proved to be one of the most fruitful areas of biological research in recent years. The present volume brings together contributions from key researchers in the field.

October 1989 272pp Hardback 0-412-36500-6 £35.00

Metals and Microorganisms

Martin Hughes and **Robert K Poole,** *both at King's College, University of London, UK*

This book is the first interdisciplinary, integrated coverage of the ways in which microorganisms react with metals. After a discussion of the underlying inorganic chemistry, the supply, transport and functions of metals are considered.

September 1989 424pp Hardback 0-412-24400-4 £35.00

Primate Origins and Evolution

A phylogenetic reconstruction

R D Martin, *University of Zurich, Switzerland*

Primate Origins and Evolution presents a thoroughly documented and thoughtful synthesis of molecular and systematic approaches to the subject and will be a major contribution to the literature on primate evolution.

December 1989 832pp, c.275 illus Hardback 0-412-12710-5 £89.00

Prochloron

A microbial enigma

Edited by **Ralph A Lewin** and **Lanna Cheng,** *both of Scripps Institution of Oceanography, University of California, San Deigo, USA*

The unicellular *Prochloron* is the best studied species of the Prochlorophyta, the latest subclass of algae to be discovered. The results of the past 12 years are now published in one edited book which includes a historical introduction, colour photographs and electron-micrographs.

August 1989 129pp, 64 illus. Hardback 0-412-01901-9 £42.00

New Facsimile Reprint of a Chapman and Hall Classic

Social Behaviour in Animals

N Tinbergen

With a new preface by Professor G P Baerends.

January 1990 184pp, 8 half-tones, 67 line drawings
Paperback 0-412-36920-6 c.£12.50

Stage-Structured Populations

Sampling, analysis and simulation

Bryan F J Manly, *University of Otago, New Zealand*

Provides a review of methods for obtaining and analysing data from populations taking account of the fecundity, death-rate, etc. of individuals at different stages (larva/adult/instar, etc).

Population and Community Biology Series

December 1989 240pp Hardback 0-412-35060-2 £37.50

MARTINDALE

The Extra Pharmacopoeia

The world's most comprehensive source
of drug information in a single volume

Twenty-ninth Edition

Prepared by the editorial staff of the Royal Pharmaceutical Society of Great Britain, and edited by Dr James E.F. Reynolds

The 29th edition contains information on more drugs in more depth than in any previous edition. Information includes:

- 4000 monographs on drugs and ancillary substances.
- 62,000 drug names, synonyms, codes and preparation names.
- More than 4600 manufacturer's names and addresses throughout the world.
- Many more referenced reviews of topics that are a matter of debate.

Features new to this edition include the rearrangement of chapters to reflect current drug usage and a more open arrangement of the text to simplify the process of finding information within a monograph.

1930 pages (clothbound) **£95.00** (UK only)
0 85369 210 6 **1989**

Copies of Martindale may be obtained through your local medical bookseller or, in any case of difficulty, direct from the publishers.

CONTENTS

Preface
Provides terms of reference and tables of contents; nomenclature of chemical ions and groups; abbreviations; atomic weights; dissociation constants; body-surface area calculations; SI units; millimoles and milliequivalents; Imperial and other equivalents.

Part I
Monographs on Drugs and Ancillary Substances: A vast collection of 4000 drugs with similar uses or actions arranged in 72 chapters. *(1535 pages)*

Part II
Supplementary Drugs and Ancillary Substances: A series of short monographs on some 800 drugs and ancillary substances arranged in the alphabetical order of their main titles. *(95 pages)*

Part III
Formulas of Proprietary Medicines: Composition of about 670 proprietary medicines sold over-the-counter in the United Kingdom. *(11 pages)*

Directory of Manufacturers: Names and addresses of manufacturers abbreviated throughout the text.

Index to Clinical Uses: Refers to drugs mentioned in the text of Parts I and II.

Index to Martindale Identity Numbers: Links monographs with Martindale Online.

General Index: Refers to drugs, preparations, compounds, and pharmacological and therapeutic groups in the book. *About 62,000 entries*

MAJOR NEW TITLES

BIOLOGY

TECHNIQUES IN IMMUNOCYTOCHEMISTRY Volume 4

G.R. Bullock and P. Petrusz

The fourth volume in this acclaimed series detailing methods in cell biology elucidates further exciting advances in immunocytochemistry and associated techniques.

August 1989, 296 pages, ISBN: 0-12-140407-2, £32.50

THE BOTTLENOSE DOLPHIN

Edited by Stephen Leatherwood and Randall Reeves

This volume presents the most recent biological and behavioral discoveries of bottlenose dolphins from different regions and compares bottlenose dolphins as a group with other species of animals.

November 1989, 653 pages, ISBN: 0-12-440280-1,
£64.50 (tentative)

ARABIAN MAMMALS

A Natural History

Jonathan Kingdon

This beautifully illustrated book will be a delight to natural history lovers as well as a standard reference for mammologists and conservationists interested in Arabian wildlife.

February 1990, 300 pages, ISBN: 0-12-408350-1,
£65.00 (tentative)

MOLECULAR BIOLOGY:

A Selection of Papers

Compiled by Sydney Brenner

Founded in 1959, by John Kendrew, ***The Journal of Molecular Biology*** was the first journal devoted to this new and revolutionary science. To celebrate the thirtieth anniversary of the Journal, the editor, Sydney Brenner, has selected a number of papers from the first hundred volumes. Includes papers by Jacob, Monod and Crick.

Of value to all biologists with an interest in the molecular basis of living systems, the book is a personal selection by the Editor.

Paperback, November 1989, 640 pages,
ISBN: 0-12-131200-3, £15.95

BRAIN BROWSER™

Floye E. Bloom, Warren G. Young and Yung M. Kim

Brain Browser™ includes an electronic version of ***The Rat Brain in Stereotaxic Coordinates***, Second Edition by George Paxinos and Charles Watson (Academic Press, 1986)

Brain Browser™ is a Hyper-Card®-based program for the Macintosh® computer. It has been designed to assist beginning and advanced neuroscience students as well as neuroscience researchers in their efforts to organize, analyse, and contribute to the growing, detailed knowledge of the brain.

December 1989
Brain Browser™ Program: £215.00 (tentative),

MITOSIS

Molecules and Mechanisms

Edited by J.S. Hyams and B.R. Brinkley

Written and compiled by leading authorities, this book reviews the state of mitosis research, discussing cytological, ultrastructural, physical, genetic, and biochemical approaches, and focusing on areas of study that are currently under the most intensive investigation.

July 1989, 368 pages, ISBN: 0-12-363420-2, £45.00

ARCHAEOLOGY

Second Edition

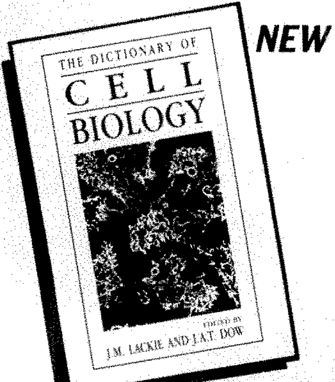
PRINCIPLES OF ARCHAEOLOGICAL STRATIGRAPHY

Edward Harris

This book is the second edition of the only text devoted entirely to archaeological stratigraphy, a subject of fundamental importance to most studies in archaeology.

The opening chapters of this edition discuss the historical development of archaeological stratigraphy. The central chapters examine the laws and basic concepts of the subject, and the last few look at methods of recording stratification, constructing stratigraphic sequences, and at the analysis of stratification and artifacts.

October 1989, 184 pages, ISBN: 0-12-326651-3, £17.50



NEW THE DICTIONARY OF CELL BIOLOGY

Edited by J.M. Lackie and J.A.T. Dow

Cell Biology forms the link between the molecular life sciences and the rest of biology and medicine. Its vocabulary is hence broad and borrows widely from other disciplines. ***The Dictionary of Cell Biology*** presents nearly 4000 terms which cover classical cell biology and spill over into the adjacent fields of molecular biology, genetics, neurobiology, physiology, immunology and pathology. Synonyms are provided where necessary and cross-references link terms that are related.

This Dictionary will not only serve as an essential reference to students of cell biology, but as an invaluable *aide memoire* to research workers in this and related areas. For the curious amateur and scientific journalist it provides a key to the technical literature and a guide to spelling and terminology.

December 1989

BIOCHEMISTRY

Announcing a Major New Series

METHODS IN PLANT BIOCHEMISTRY

Series Editors: P.M. Dey and J.B. Harborne

This new series, ***Methods in Plant Biochemistry***, will provide an authoritative reference on current techniques in the various fields of plant biochemical research. Each volume in the series, under the expert guidance of a guest editor, will deal with a particular group of plant compounds.

Volume 1: PLANT PHENOLICS, Edited by J.B. Harborne, Dec 1989, 564 pages, ISBN: 0.12.461011.0, £65.00

Volume 2: CARBOHYDRATES, Edited by P.M. Dey, March 1990, c.656 pages, ISBN: 0.12.461012.9, £85.00 (tentative)

Volume 3: ENZYMES OF PRIMARY METABOLISM, Edited by P.J. Lea, February 1990, c.416 pages, ISBN: 0.12.461013.7, £55.00 (tentative)

The state-of-the-art PCR laboratory manual

PCR PROTOCOLS

A Guide to Methods and Applications

Edited by Michael A. Innis, David H. Gelfand, John J. Sninsky and Thomas J. White

The broad utility of the polymerase chain reaction method is now within the reach of every researcher. Designed for use at the laboratory bench, this is the most comprehensive manual on PCR available today.

September 1989, c. 320 pages
Comb bound, ISBN: 0-12-372181-4, £25.00 (tentative)
Casebound, ISBN: 0-12-372180-6, £43.50 (tentative)

GEOLOGY/GEOPHYSICS

THE EARTH'S IONOSPHERE

Plasmaphysics and Electrodynamics

Michael C. Kelley

A Volume in the INTERNATIONAL GEOPHYSICS Series

In the past two decades, the underlying physical principles on which ionospheric research is based have undergone a drastic change. With the development of incoherent scatter radar techniques as well as scientific satellites, a whole new realm of ionospheric processes became amenable to scientific study. In particular, space scientists were able to reliably probe the dynamics of the ionosphere and to realize the fundamental role played by electric fields. In a parallel development, the physics of plasmas became an important branch of science due to its role in controlled fusion research.

October 1989, 487 pages,
Casebound, ISBN: 0-12-404012-8, £64.50
Paperback, 0-12-404013-6, £29.00

STORM AND CLOUD DYNAMICS

William R. Cotton and Richard A. Anthes

A Volume in the INTERNATIONAL GEOPHYSICS Series

The focus of this book is on the dynamics of clouds and of precipitating mesoscale meteorological systems.

October 1989, 883 pages, ISBN: 0-12-192530-7, £107.50

FRACTURE MECHANICS OF ROCK

Edited by B.K. Atkinson

This book presents a concise treatment of the physics and mathematics of a representative selection of problems from areas such as earthquake mechanics and prediction, hydraulic fracturing, hot dry rock geothermal energy, fault mechanics and dynamic fragmentation.

May 1989, 534 pages
***New in Paperback*, ISBN: 0-12-066266-3, £19.95**
Casebound, 1987, 534 pages, ISBN: 0-12-066265-5, £64.50

ECOLOGY

ENVIRONMENTAL ECOLOGY

The Impacts of Pollution and Other Stresses on Ecosystem Structure and Function

Bill Freedman

This book focuses on the effects of pollution and other disturbances on the environment, including toxic gases and metals, acidification of watersheds, oil pollution, pesticides, and other chemical waste. It includes examples and case studies, an extensive bibliography (1000+ entries), a glossary, and chapter summaries.

August 1989, 400 pages, ISBN: 0-12-266540-6, £29.00

CHEMISTRY

COLLOIDAL HYDRODYNAMICS

T.G.M. Van de Ven

A Volume in the COLLOID SCIENCE Series

This book provides a systematic treatment of the flow behavior of colloidal dispersions that occur in a large number of industrual processes, such as transporation, stirring, and shaking. It also discusses the microrheology of dilute and concentrated dispersions. ***Colloidal Hydrodynamics*** is a useful reference for graduate students in chemistry and chemical engineering as well as researchers in the field.

July 1989, 600 pages, ISBN: 0-12-710770-3, £43.00

COMPUTING

THE DESKTOP FRACTAL DESIGN SYSTEM

Michael Barnsley

Includes Desktop Fractal Design Handbook and one floppy disk

This software system will be an indispensable tool for students, engineers, and scientists in all disciplines. The software which runs on IBM and compatible PCs with an enhanced graphics board and 640K memory helps to connect theoretical concepts with on-screen geometric modeling.

NEW BOOK . . . from COSMATOM

THE NATURE OF THE FIFTH DIMENSION

DE REVOLUTIONIBUS ORBIUM ROTANTIUM

IAN McCRIMMON

Five-dimensional theory stands modern science on its head and explodes the myths of the electronic mass and the nature of light. It treats the proton and electron as an oscillating particle, making waves, passing continually back and forth through the five-dimensional speed of light. The electron mass, at present regarded as a small fraction of the proton mass, is shown to be an illusion of four-dimensional space-time. The electron exists, as an equal and opposite mass, on the other side of the speed of light. It is, in fact, the same particle in a [$-c$] frame of reference.

Why does the speed of light have precisely the value that it does? $H \longleftrightarrow \bar{H}$, through $_5c$, defines the speed of light, when all mass (five-dimensional mass) is converted to kinetic energy.

Current earthquake theory chatters on about lithospheric plates and fault lines, defining them by reference to earthquake activity, a circular argument if ever there was one. Five-dimensional theory explains, *inter alia*, the thermodynamic interaction of planetary bodies and how the Moon draws away electrons from the Earth, causing largely the tides and weather systems of the globe; the Earth is bound, thermodynamically, to repel the colder Moon by "firing" electrons into space, although likewise receiving them from the hotter Sun (cf. Prevost's Theory of Exchanges). The important area of the world for "originating" earthquakes (as opposed to "compensating" ones) is the belt around the Earth at latitude 40 °N, through Italy, Turkey, USSR, China, Japan and San Francisco (37½ °N). This latitude coincides with the crossover point of the two curves on the graph of solar radiation absorbed by the Earth against long wave radiation leaving the atmosphere. There is a net heat loss north of this latitude which must be compensated by heat leaving the equatorial regions. Water (e.g., the Pacific Ocean) is particularly involved in the struggle to retain the departing electrons, and basaltic areas are especially liable to be affected in this tug-of-war.

Regarding the San Francisco earthquake (October 17), the Moon was at perigee on October 15, and as it began drawing away again, its apparent declination North, with regard to the ecliptic, reached its maximum on the day of the earthquake and began moving South again, drawing electrons with it. A similar position arises again on November 13 and December 11, but the effect of these may be dissipated by the energy released by the earlier quake. Contrary to present opinion, the San Andreas, and other faults, are not the 'cause' of earthquakes, but the effect of electrons being constantly torn out of the Earth in the necessity to feed the thermodynamic equilibrium of the planets. Volcanoes, similarly, do not explode because of actions within the Earth; they are torn out like teeth by external forces.

Reader Service No.22

After the two cultures

Adam Kuper

Academic Tribes and Territories: Intellectual Enquiry and the Cultures of Disciplines. By Tony Becher. *Open University Press: 1989. Pp.200. Hbk £27.50, pbk £9.95.*

Tony Becher's enquiry into the mores of academics is a belated reaction to C.P. Snow's division of intellectual life into two great camps, arts and science, which (if they ever existed) have now long been abandoned for smaller, more intimate, redoubts. An anthropologist, Clifford Geertz, has pointed out that "most academic communities are not that much larger than most peasant villages and just about as ingrown", with their characteristic totems, initiation ceremonies and ancestor rites, modes of work, codes and systems of authority. Professor Becher pursues Geertz's suggestion that these societies should be treated rather in the way that anthropologists study exotic tribes, as social units that have distinctive cultures.

For his enquiry he selected 12 disciplines — biology, chemistry, physics and mathematics, representing the pure sciences; mechanical engineering and pharmacy, as applied sciences; economics and sociology, from the social sciences; history and modern languages from the humanities; and law, representing the social and administrative professions. It is immediately obvious that these categories are not watertight (mathematics, economics and history could all be reclassified), and Becher's thesis is in fact that the most significant criteria for classifying academic pursuits cut across not only the science–arts divide but also disciplinary boundaries, and that they define most clearly the subdisciplines which we call specialisms. This is where the academic has his true being.

Becher's main criteria are familiar: hard versus soft, and pure versus applied pursuits. Hard specialisms use quantitative rather than qualitative methods, clearly define problems and deliver cumulative additions to a body of knowledge. They also tend to be free of value conflicts. Soft specialisms use qualitative methods, address diffuse issues which are often dictated by social concerns (and therefore invite political controversy) and they do not usually yield a body of uncontested knowledge. A more original distinction is that between 'hard, applied' specialisms, which proceed by trial and error, and deliver products which are assessed in terms of their efficiency, and 'soft, applied' professions which use case law, are evaluated in political and moral terms, and produce protocols rather than instruments. Most interesting is Becher's distinction between 'rural' and 'urban' specialisms, the urban specialism being one in which large numbers of workers, operating in competitive teams, address the same closely defined problems, publishing rapidly and often informally, while the rural worker practises his individual craft in a village workshop, where the postman seldom calls.

By applying these criteria to subdisciplines, Becher captures something of the perceived reality of academic life, where the most sensitive boundaries are often drawn within the discipline. He quotes biologists on biologists — "microbiologists are narrow, but geneticists are lively"; "zoologists are more adventurous and less conventional than botanists" but tend to be "arrogant and overconfident"; botanists "hide behind herbarium cases and hate one another". These stereotypes point to some real differences between specialisms which have to do at once with the type of work involved and with the type of people who choose that sort of work (or who are moulded by what they do).

The cultural peculiarities of the tribe are also a matter of organization. Careers, for example, follow characteristic trajectories in particular disciplines. The phenomenon of burn-out, the scientific menopause, which pushes middle-aged men into administration, or philosophy, is most characteristic of hard, pure specialisms. In soft, pure fields scholars become more expert with time, so that a historian may expect to reach his peak only in his fifties. Publications take a different form in different fields. Soft, pure fields typically require books, while hard, pure fields know only short papers. The former are typically written by one scholar over many years, the latter by teams of collaborators on short-term projects. Soft disciplines tend to be dominated by a small number of Grand Old Men, the hard disciplines are multi-centred, throwing up charismatic leaders with shorter tenure and more rivals.

Of course, all academic disciplines also share in the general academic culture, about which Becher has some useful reminders, starting with one of the universals of academic life, "that nearly everything is graded in more or less subtle ways".

His central premise is that "the main currency for the academic is not power, as it is for the politician, or wealth, as it is for the businessman, but reputation". Academic reputation depends on the quality of publications, but it is also affected by institutional affiliation. Publications emanating from famous laboratories or think-tanks start life with a silver spoon in their mouths. Reputation in turn brings

Analog VLSI Implementation of Neural Systems
edited by **Carver Mead** and **Mohammed Ismail**
THE KLUWER INTERNATIONAL SERIES IN ENGINEERING AND COMPUTER SCIENCE 80
In *Analog VLSI Implementation of Neural Systems* Carver Mead and Mohammed Ismail present leading research contributions encompassing the entire range of topics currently under study in this exciting new discipline. All contributors' descriptions include detailed characterization of a working chip. Furthermore, no design has previously been published. As a result, this volume presents the most recent innovative work in this emergent field. Each contribution devotes considerable attention to design shortcomings, as well as to notable successes achieved.
1989, 272 pp. ISBN 0-7923-9040-7
Hardbound Dfl. 150.00/£39.25/US$55.00

Transition Metal Complexes as Drugs and Chemotherapeutic Agents
by **Nicholas Farrell**
CATALYSIS BY METAL COMPLEXES 11
Aspects of both chemotherapy and pharmacodynamics are included and the book unites for the first time in one volume a description of the wide range and applicability of metal complexes.
1989, 304 pp. ISBN 90-277-2828-3
Hardbound Dfl. 180.00/£59.00/US$89.00

power over the careers and reputations of others. Within the political systems of disciplines and specialisms, peer groups may serve as democratic controls, particularly in reviewing, but power tends to concentrate in very small networks.

Suggestive though it is, this short study is nevertheless only a preliminary excursion into the field. Becher restricts himself to élite institutions. His fieldwork was done in Britain and the United States, but he gives an undifferentiated account of the Anglo-American university world, although the national variations are surely very striking. A future study, more sensitive to the national character of academic enterprises, should also consider Dutch, German or Scandinavian universities, with their civil service cultures, or European think-tanks, like the Max-Planck Institutes, on which *Nature* has been publishing some unsettling ethnographic reports. A reading of Pierre Bourdieu's *Homo Academicus,* a dense and original recent study of the French academic system, will convince the foreigner that they do things very differently in France. For the purposes of Becher's argument, it is, for instance, noteworthy that the prestige hierarchy of disciplines diverges from the Anglo-Saxon model, and also that the leading research teams are to be found outside the university sector.

Becher does not draw together his scattered comments on the connections which might be made between the peculiarities of various academic tribes and the nature of the territories they inhabit. Here again a comparative approach would have suggested fresh questions. Are German physicists more like German economists in their career patterns and organizational hierarchies than they are like American physicists? Or is it something about physics, or economics, that is decisive? Professor Becher briefly discusses the different environments of the various disciplines — the market pressures on engineers, the professional demands made of lawyers and so forth. But these also vary between different national political systems and markets, as may be seen from the contrasting views of academic engineering in Britain and in Germany.

One important implication of the study is nevertheless clear. These various enterprises are not readily measured by the same criteria because they differ so markedly (and probably necessarily) in their goals, methods, work habits and relationships to the outside world. Bureaucrats will have to refine their measures of efficiency if they are to do justice to this diversity of academic society. ☐

Gossip value

Lewis Wolpert

Life Among the Scientists: An Anthropological Study of an Australian Scientific Community. By Max Charlesworth, Lyndsay Farrall, Terry Stokes and David Turnbull. *Oxford University Press, Australia: 1989. Pp.304. Pbk A$19.95. To be published in Britain and the United States next year.*

A MEASURE of one's understanding of other groups is how well you appreciate their humour. This applies as much to scientists as any subset of people, for jokes and wit are a prominent feature of laboratory and institutional life. Yet humour is not mentioned in this book. The scientists at the Walter and Eliza Hall Institute of Medical Sciences in Melbourne — the group considered — may of course be unusual, but a more likely explanation is that the social scientists who carried out this anthropological survey simply failed to understand much of what they were studying.

Associated Press

Macfarlane Burnet — Nobel winner.

The authors, who have adopted the curious convention of writing in the first person, like a conflated committee, set out with the provisional hypothesis that scientific knowledge is socially 'constructed'. This is a fashionable view among many sociologists of science and implies that science has rather little to do with the real world that scientists study, but instead is shaped by a complex set of social factors. This relativist stance is then used to argue that scientific knowledge has no particular virtue or validity. These authors take a more equivocal position but basically stick to this idea, and the possibility that science provides understanding of natural phenomena is virtually ignored.

The Walter and Eliza Hall Institute is very distinguished, its contributions to science covering a wide range of topics in molecular and cellular immunology. The first director (1944–1965), Sir Macfarlane Burnet, won a Nobel prize for his clonal selection theory and in the book there is an attempt to view him as a local hero whose social function is to legitimize a particular conception of science — the idea of an individual scientist making a discovery which revolutionizes the field. Burnet was hostile to molecular biology and his general style is contrasted with that of the current director, Sir Gus Nossal. But the analysis provides no insight into how Burnet came to make his great discovery or into the basis of his antipathy to molecular biology. It may not have been his dislike of complex apparatus and expensive equipment, as Charlesworth and his colleagues suggest, but rather his inability to see the power of molecular biology. He simply did not believe that it would be possible to understand cells in molecular terms — they were, for him, impossibly complex.

One of the main conclusions of the study is how large a part 'power' plays in the scientific process, for example in what the authors call the legitimization of molecular biology. They are persuaded that Foucault's insight is "profoundly true", namely that the establishment of specific discourses — ways of speaking and thinking — also provides access to power and control over the objects of those discourses. For them "the new model that came to dominate biology after the discovery of DNA only became established after a good deal of politicking and propaganda", in which 'public relations' used by scientists had a large part. The brief analysis of this period is most unsatisfactory and fails to take into account the change in paradigm from metabolism to information. The authors also do not understand the revolution molecular biology caused, and instead concentrate on the idea that molecular biology was a philosophical movement based on the conviction that all biology could be explained in terms of physics and chemistry. Thus it is said that Crick used Schrödinger's name to legitimize his reductionist approach. Of course there was evangelizing and politicking but none of that would have been effective had molecular biology not provided fundamental new insights. Moreover, scientists are aware of these issues and the nature of scientific politics, fashions and power. That's what they often gossip about.

There is a touching, but nevertheless irritating naivety to the conception of science purveyed in the book. For example, the authors are apparently appalled by "the contradiction between the ideal norms of science, that scientific knowledge should be disinterested . . .

and the spirit of competitive individualism", and imply that competition between scientists (the " 'winner takes all' ethos") is something new. Yet one of the rewards in science has always been priority in discovery — are Charlesworth *et al.* really unaware of the great historical controversies, such as that between Newton and Leibniz over who discovered the calculus? And where do these 'ideals' and 'norms' come from? These really important social constructs are neither questioned nor analysed.

Competitiveness is the subject of a section of the book dealing with immunoparasitology and the quest for a malaria vaccine. Nossal's refutation of their views, which they quote at length, seems to have made no impression. Nossal recognizes competitiveness but emphasizes the tremendous amount of collaboration that science involves. "Now the question is, does the winner take all? Of course not! The peer group is not stupid. . . . The second or third in the race may not win the Nobel prize, but there are plenty of important subsidiary rewards".

This book was intended to convey a sense of the "life-world" of a group of scientists as well as some idea of how that world is "constructed". In this it fails. Much of the description is like that found in an annual report, and any half-decent journalist would have done a far better job. Rather, its value lies in what it reveals about anthropology and social science. Did the authors bring any new insights or techniques from their discipline? There is hardly a word about how the study was carried out or over what period. Did they listen to the gossip? All sorts of important questions are not touched upon. How, for example, does the Institute deal with scientists that are no longer productive; how are resources distributed; to what extent is the research directed; were there different styles of sciences; what are the rewards that scientists seek? An apparent desire for objectivity seems to have killed any curiosity, and any interest.

What, for example, can one say of the following? "What impresses me more and more about a good deal of science at the Institute is the concentration on 'getting data' " and "the idea of data generation seems to me to be a crucial feature of science and is often overlooked. The laboratory is a kind of data factory". No one should be surprised that data are important for biologists, while the metaphor of a "data factory" is plain fatuous. If this is all that anthropology has to offer for studying other groups, then the result is depressing. ☐

The Fate of the Forest: Developers, Destroyers and Defenders of the Amazon. By S. Hecht and A. Cockburn. *Verso, London: 1989. Pp.256. £16.95, $24.95.*

Saving the Tropical Forests. By Judith Gradwohl and Russell Greenberg. *Island Press, Washington, DC/Earthscan, London: 1989. Pp.214. Hbk $24.95; pbk £6.95.*

WE ARE being overwhelmed by books on tropical forests, some of them less than whelming. The rush to publication reflects the recent burst of interest in the forests as we become aware of their impending demise and their intrinsic wealth.

One of the reasons why we have not done a better job of safeguarding the forests is that we understand all too little of what we are dealing with — at least as compared with savannahs, grasslands, temperate woodlands and tundras — or of what is at stake. There is still only a sparse selection of solid scientific writings on the forests' makeup, their biotic richness, their ecological complexity, their community structures, their dynamic interactions and — above all — their relationships to the human enterprise. For example, we have only a vague notion of how biotically diverse the forests are. Just this year Professor Steve Hubbell of Princeton University revealed that a 50-hectare plot in Peninsular Malaysia contains over 800 species of woody plant, or as many as in all of North America. And when we finally gain a true grasp of the forests' ultimate richness, we shall finally gain a true realization of how far we have to go before we understand their diverse interactions.

Tropical Forests: Botanical Dynamics, Speciation and Diversity provides an abundance of the types of data and analyses that must underpin programmes for conservation and sustainable use. The opening section on forest dynamics appraises the physical factors such as soil and water regimes, together with patterns of tree distribution, gap-phase dynamics, canopy composition and dynamic stability of forest structures overall. There follow extended sections on speciation and diversity, primary and secondary formations, and community dynamics, before the book winds up with a retrospect-and-prospect summation. All of the chapters are authoritative to a degree — among the contributors are Gentry, Halle, Hartshorn, Mori, Oldeman, Polhill and Raven — and they challenge the reader with the thought that tropical forests remain virtually a terra nova to modern science.

Tropical Rain Forest Ecosystems, published in Elsevier's *Ecosystems of the World* series, reflects the experiences of another lengthy list of luminaries — Bruenig, Ewel, Golley, Janzen, Jordan, Kartawinata, Kira, Prance, Sanchez and several others. The book's structure is similar to that of the first. It starts with the physical environment (notably climate among other limiting factors), moves on to tree architecture, taxonomy and classification, then to accounts of interactions such as epiphytism and symbiotic relationships, which lead into a consideration of some plant categories such as lianas, bryophytes and lichens, as well as of mammal categories such as primates, bats and flying insects. These expository reviews are interspersed with assessments of the three main tropical forest regions, and of a number of the countries concerned.

These two books make plain how few scientific answers we yet possess, and how far we are from even asking all the right questions about tropical forests. Regrettably and remarkably, however, neither of them says much about the actual rate at which the forests are disappearing, even though there is now a host of remote-sensing and other inventorying technologies that can provide the relevant data. I estimate that during the 1980s deforestation has accelerated by roughly 50 per cent, not only in Brazil but in Bolivia, the Ivory Coast, Burma, Thailand, Eastern Malaysia and the Philippines. Incidentally, the United Nations agency charged with responsibility for tropical forests, the Food and Agriculture Organization, asserts there has been no evidence of any increase in the deforestation rate during the 1980s — and it does not intend to publish a revision of its 1982 report before 1992 at the earliest.

Nor do the two books attempt any analysis of why the forests are disappearing so rapidly. The editors might legitimately claim that they are natural-science assessments. All the same, it seems strange that in 1989 they should include no multidisciplinary evaluation of the whys and wherefores of deforestation — the economic, political, social and institutional factors at work. One could argue that it is partly because of this deficiency in the past that the forests are now disappearing; ecologists and economists have been far too reluctant to make common cause in presenting an integrated assessment of what the forests amount to and hence how they can be safeguarded.

All the more welcome, then, is the third

Felled rainforest — making a fast profit, but leaving greater wealth unrecognized.

book under review, *The Fate of the Forest: Developers, Destroyers and Defenders of the Amazon*. Confined to a single, though the largest and most controversial sector of the biome, many of the authors' insights and conclusions apply elsewhere. The true wealth of the Amazon is little appreciated by the region's political leaders; on the contrary, they often view the forest as a barrier to progress (a term they rarely if ever define). Moreover the recent outbreak of destruction is a departure only in scale. For hundreds of years there have been hands ready to wield the machete and matchbox, and to make a fast profit from just a few forest products while disregarding the many others that could offer a greater return — and do so sustainably.

Hecht and Cockburn's historical perspective is illuminating, and they are to be congratulated on their dispassionate appraisal of the forces bent on deforestation. Salvation for the forest will not depend so much on what goes on inside it, still less on the efforts of conventional foresters. It will come from the land-use planners, economists and development technocrats who operate at the macro-level of national policy, and it will reflect the determinants of agriculture, population, urbanization, financial stability, social equity and political security. These factors will have far greater effect than will logging methods, silviculture, genetic breeding and wood chemistry, or zoning systems, nature preserves and policing efforts. Most important of all, such factors will be determined in places far from the forests, even beyond the countries principally involved, for example in the citadels of foreign investment and the sources of foreign debt.

Finally, *Saving the Tropical Forests* offers a host of specific solutions to the problem declared by its title. The book contains case-studies of 38 examples of success at the local level, covering such broad themes as natural forest management, forest restoration, sustainable agriculture and forest reserves. Among the specific topics addressed are agroforestry, home-garden systems, extractive reserves, watershed management, medicinal plants, multiple-use conservation units, buffer zones and esoteric experiments such as iguana ranching. The book is aimed at conservationists, biologists and policy makers, and presents a fine compendium of recent information on management measures and conservation strategies that demonstrably work — albeit on a small scale — in a variety of economic, sociocultural and political contexts.

But it is a commentary on these four books, excellent within their limitations though they are, and on the traditionalist approach to tropical forests, that none of them ventures a mention of what may soon prove to be the biggest factor of all in the forests' future — the climate connection. It is becoming apparent that tropical forests play a gyroscopic role in regulating climate, whether at local, national, regional or global level. The consequences could be crucial not only for the two billion people who live in the humid tropics, but also for the rest of us. Herein could lie the single most compelling reason for a 'safety first' response to all questions of forest management and conservation. Within ten years, we may well find that the most productive way to exploit the forests is to leave them to get on with their job of maintaining precipitation patterns, temperature balances and the carbon budget of the atmosphere. ☐

Norman Myers is at Upper Meadow, Old Road, Headington, Oxford OX3 8SZ, UK.

• Recently published by Barrie & Jenkins, London, *The Rainforests: A Celebration*, edited by L. Silcock, is a superbly illustrated book of the rainforests' beauty and variety, price is £19.95.

Control of Pain and Other Symptoms in Cancer Patients

Tor Inge Tønnessen, *Norwegian Radium Hospital, Oslo, Norway*

The Cancer Series

"The greatest profit to be obtained from this book is that it bridges the gap between theory and clinic and that it so comprehensively attempts to throw light on the experience of pain and the problems surrounding palliative treatment of cancer patients. The importance of adequate diagnosis of pain is emphasized...particularly valuable, since we are becoming increasingly aware that palliative treatment of cancer symptoms must be carried out just as actively as curative and remission-oriented therapy. I can warmly recommend this book to all those who are in any way involved in the care of cancer patients. The book should be an obligatory textbook in the education of both doctors and nurses." Philip Gummett

Research Foresight: Priority-Setting in Science. By Ben R. Martin and John Irvine. *Pinter, London: 1989. Pp. 366. £35, $45.*

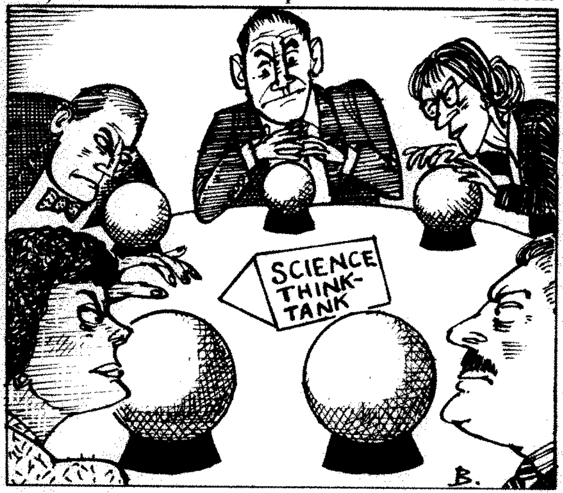
In his *New Atlantis*, Francis Bacon describes the order or society called Salomon's House. This seventeenth-century prototypical research organization operated a well-planned division of labour. Some of the fellows surveyed the literature; others devised or performed experiments; yet others explored the theoretical implications of research results; and some (called 'Benefactors') sought applications of this work. Another important role was performed by those who travelled abroad, in disguise, to collect the books and experiments of other countries. These were called Merchants of Light.

Today, when the state demands increasing returns from its investment in science (so that the 'Benefactors' might be renamed 'Exploiters'), Bacon might think it wise to add a cadre of policy analysts. They would need their own Merchants of Light, for science policy is now an international business. Two candidates might be the authors of the book under review, who have travelled the world, in the guise of contractors to the Dutch government, bringing back information on how eight countries engage in 'foresight' in science and technology. Oddly, having gone to France, West Germany, the United States, Japan, Australia, Canada, Sweden and Norway, they omit their own country, Britain. Their excuse (lack of time and difficulties over commenting on foresight exercises in which they had been involved) is not entirely compelling.

'Foresight' is a slightly curious term. For one thing, what should we call the people who do it? 'Foreseers' sounds too biblical, while 'forecasters' misses a crucial distinction. As the authors explain, the aim is not to forecast, nor — as was suggested by the subtitle of their previous book, *Foresight in Science: Picking the Winners*, published by Pinter in 1984 — to pick winners. Rather, it is to establish a continuous process for reaching an improved understanding of possible developments in science and technology, and the forces likely to shape them, in an attempt to nurture winners and hence create the future.

In their travels, Martin and Irvine encountered a great deal of activity of these types, expecially in relation to strategic and applied research (less so for basic research). There were, though, considerable variations between countries in terms of methods and institutions used, and commitment to the foresight process.

Some countries use formal bibliometric methods to try to spot growth points in science, nationally and internationally. Some engage in elaborate consultative exercises, involving large numbers of scientists and users of science and technology. Some adapt various tools from the kitbag of forecasters and futurologists. Some set up specialist panels on narrow subjects, while others try to take a view of the whole national scene. Some draw on professional analysts (especially Japan, which has a network of some 300 public and private think-tanks, many of them with levels of expertise that are unmatched even by the large US consultancies). Some use what a respondent in the United States called the BOGSAT method (Bunch of Guys Sitting Around a Table).



What lessons can be extracted from this bewildering variety? The Director-General for Science Policy of the Dutch Ministry of Education and Science, in introducing the book, singles out three. First, analysis of long-term needs and opportunities for research should be part of a well-planned process that includes implementation of the choices made. The authors identify a number of attempts at foresight that failed because it was not clear from the outset what was to be done with the results. Second, it is essential, especially for smaller countries, to carry out systematic global monitoring of developments in research. This is something that the Japanese have been doing since the 1950s. Third, and as already indicated above, the aim of policy should be to nurture scientific winners rather than simply to try to pick them, ready-made as it were. That is, a process of identifying, and then supporting, areas deemed to be of national importance should be established.

Other lessons include, first, the point that introducing foresight approaches can be a slow and painful process, especially in countries with no culture of planning or consensus-seeking. This is particularly so in relation to setting priorities in basic research, even in Japan. Second, the authors show the importance of trying to integrate the different levels of the policy process, from all-embracing national socio-economic goals, down through various sectoral institutions and objectives, to strategic and basic research. But they also show the crucial importance, in seeking this integration, of achieving a balance between the views of innovative young scientists, who can see the possible directions in which science might go, and the more seasoned views of senior officials, industrialists and other users, who can relate science-push to social demand, particularly across the boundaries of established disciplines.

From a parochial angle, it is a pity that Britain was excluded from the study. Britain is a country in which formal foresight methods of a bibliometric type have been used by, for example, the Royal Society and the Advisory Board for the Research Councils. The Cabinet's Advisory Council on Science and Technology, and its predecessor, have conducted a number of studies with the intention of guiding policy over research priorities. The University Grants Committee, now the Universities Funding Council, has engaged in substantial restructuring of basic research, though without (as far as one can tell) any vision of the national future that it is aiming to create. And, in response to the arguments in Irvine and Martin's 1984 book, the Centre for Exploitation of Science and Technology — which is mainly funded by industry — has been set up to try to articulate industrial views of the future and integrate them with government policy. The views of our Merchants of Light on these measures would have been welcome.

We can be sure that foresight is here to stay (which may make it worth trying to find a better name for it). The perception is growing that the procedure does not imply draconian planning. Instead it aims at improving communications between producers and users of research and arriving at decisions based on a consensus about the choices to be made. The winners, so the advocates of foresight claim, will be the countries that manage this process best. ☐

Philip Gummett chairs the Board of Science and Technology Policy, University of Manchester, Manchester M13 9PL, UK.

- Recently published by Routledge, London, is *Innovation and Technology Transfer in Japan and Europe: Industry–Academic Interactions*, by Glyn O. Phillips. The book provides "a perspective against which we [the British] can take decisions about the future of our own industry–education interaction arrangements" and costs £45.

Fact and fiction

S.A. Barnett

The Longman Literary Companion to Science. Edited by Walter Gratzer. *Longman: 1989. Pp. 517. £17.95. To be published in the United States by Norton.*
From Creation to Chaos: Classic Writings in Science. Edited by Bernard Dixon. *Basil Blackwell: 1989. Pp. 280. £15, $29.95.*

HERE are two compendia about aspects of the scientific life. Both, especially Gratzer's, can be read with enjoyment; both are highly misleading.

Gratzer wishes to "explore the incursions of science into literature". Happily, his 216 excerpts (each of which has a brief editorial introduction) are not only from stories and poetry; many are highly readable and informative passages from biography and journalism. Readers should not be deterred by the unrepresentative false start. The first section, "The Laboratory Scene", opens with a series of exposés of "the research supervisor as a monstrous incubus". Supervisors are far more often harrassed than depraved. In default of a quantitative survey of supervision, we need a David Lodge to write a hilarious but authentic novel on the struggles of a supervisor to get her pupils to write up their work, and her final resort to writing the papers herself.

After the supervisor, we have "the research grandee and the array of his vassals". Nobel prizes, and their winners, though rare in real laboratories, loom large in this collection. Only by the fifteenth entry do we reach one of the few fictional descriptions of what research is really like: in Nigel Balchin's *A Sort of Traitors,* two research assistants patiently but resentfully record many thousands of cultures as showing "slight growth". And, much later, there is a comment on Ernest Rutherford (in Gratzer's words, "probably the greatest experimental physicist of this century"): "he got pleasure not only from the high moments, but also from the hours of what to others would be drudgery, sitting in the dark counting the alpha particle scintillations on the screen". Another rarity is a poet, Louis MacNeice, with his unromantic but not unkind portrait of a scientist who

. . . lived by measuring things
And died like a recurring decimal
Run off the page, refusing to be
curtailed;
Died as they say in harness, still
believing
In science, reason, progress.

A book such as this could hardly dwell at length on quiet people and non-events. It is appropriate that we should be horrified by the effects of anti-semitism in Poland, or of McCarthyism in the United States; that we should be frightened by an account of accidental death due to radiation; and sickened by the outcome of mindless bombing in the Second World War. In contrast, we may applaud the case of the brilliant but wayward student, admitted to a course of study though without qualifications. And we may enjoy passages from those masters of satire, Jonathan Swift and Samuel Butler, or turn for light relief to stories of the great in disconcerting situations — for instance, Albert Einstein trying to steal tobacco from Niels Bohr.

Gratzer's exertions do not seem to have been entirely a labour of love: he comes over as ambivalent towards scientists. He quotes a tribute by a classical scholar, Maurice Bowra, who said that scientists were treacherous allies on committees because "they are apt to change their minds in response to arguments", but he immediately qualifies it by reference to scientists' "passions" and, in a section on "Discovery", he states that "emulation and jealousy among scientists have [today] become sanctified as the motives that drive scientists ever onwards". Here, perhaps, is another hypothesis in need of a survey.

He finishes, as he begins, with bathos: the last section, "The Pathology of Science", contains a mixed bag of accounts of fraud and plagiarism by scientists and bogus science by illusionists, with only one (fictional) example of commercial skulduggery. Gratzer could have acknowledged that his patchwork is far from a representational portrait of science by ending with a remark by the physicist, Jeremy Bernstein, quoted on p. 151: "I pity the historians of science and others who are attempting to put together a reliable history [of science]; all you have to do, you may think, is ask the participants for their accounts of what happened. But such stories can be woefully misleading".

Capable writer — J.B.S. Haldane at University College, London 1948.

Bernard Dixon, too, is concerned with literature: by publishing his collection, he hopes to "demolish the well-worn cliché that scientists, by their nature and training, cannot write", although his medley of excerpts includes many by science writers (and even a rather dim limerick by Arthur Koestler). Most of his preface is directed at encouraging young scientists to write well. He warns adolescents against trying to imitate "models of unattainable excellence", and says that instead they should learn by analysing bad writing and read great prose for pleasure so that "lessons of style . . . sink in by subconscious osmosis". But he ignores the principal, perhaps the only, effective method of developing order, clarity and conciseness, which is to practise and to subject one's attempts to criticism.

Dixon also tells us that his book's "sole *raison d'être* is to provide pleasure for the reader". Except that they are said to be selected "solely on the basis of literary quality" the writings are unfortunately presented without editorial comment. Yet the pleasure and instruction one derives from reading are due to the combined effects, often inextricable, of style, content and context.

After the confusing preface, a reader should not be surprised to find a rather uneven selection. The passages are arranged alphabetically, hence are randomized. Six items are in verse. Of 69 prose excerpts, 18 are fragments that convey little and hardly do justice to their authors. They could well have been replaced by longer passages from writers such as Bertrand Russell and Joseph Needham who are not represented.

Among the remainder are several which, I hope, will send readers back to the originals. Here is Haldane, in 1932, on the evolutionary process: "In the first place, it is very beautiful. In that beauty is an element of tragedy. . . . In an evolutionary line rising from simplicity to complexity, then often falling back to an apparently primitive condition before its end, we perceive an artistic unity similar to that of a fugue". And here is Peter Medawar (1960), another polymath, writing less agreeably on the same subject: "It is a profound truth . . . that nature does *not* know best; that genetical evolution, if we choose to look at it liverishly instead of with fatuous good humour, is a story of waste, makeshift, compromise and blunder".

Human evolution appears in questions asked by A.R. Wallace (1875) in an unfamiliar idiom: "whether we compare the savage with the higher developments of man, or with the brutes around him, we are alike driven to the conclusion that in his large and well developed brain he possesses an organ quite disproportionate to his actual requirements — an organ that seems prepared in advance, only to be fully utilized as he progresses in civilization".

Wallace also appears in an extract from Darwin's *Autobiography* of 1876, where the author scolds himself for overlooking (in the 1840s) an important problem — "the tendency in organic lines descended from the same stock to diverge in character as they become modified. The solution, as I believe, is that the modified offspring of all dominant and increasing forms tend to become adapted to many and highly diversified places in the economy of nature". An alternative autobiographical model is provided by Otto Frisch (1979), who describes a visit to his aunt, Lise Meitner, in exile in Sweden, which led to a major discovery in atomic physics. Or one may turn to H.G. Wells (1934) on his unsuccessful attempts, as a hamfisted student in the 1890s, to make apparatus, and his all too successful campaign to burlesque his professor; or to Miriam Rothschild writing cheerfully, in 1987, on having seven years of work destroyed by a Nazi bomb.

The reader may also compare T.H. Huxley's famous account of a piece of chalk (1868) with Primo Levi's still more readable story of a carbon atom (1984). Rachel Carson's brilliant *Silent Spring* (1962) may be contrasted with E.J.H. Corner's lucid *Life of Plants* (1964). A problem outside the natural sciences is presented by S.J. Gould (1984) in a discussion of Adam's navel — an enigma indeed, for Adam was created, not born. These and other passages show that a few people with scientific training write well, even superbly. Classified and put briefly in context, they could have made a treasury to be read both for pleasure and for instruction. I especially emphasize the second purpose, for such a volume is needed to help in remedying a lamentable state of affairs — that most scientists still write badly. ☐

Blaming biology?

Daniel J. Kevles

Dangerous Diagnostics: The Social Power of Biological Information. By Dorothy Nelkin and Laurence Tancredi. *Basic Books: 1989. Pp. 207. $18.95.*

BIOMEDICAL research, especially in genetics and the neurosciences, has been generating an increasing range of new diagnostic methods and machines. Medical genetics can specify several thousand single-gene diseases and disorders, while magnetic resonance imaging, PET-scan and other techniques can detect numerous abnormalities in the brain. The new diagnostics reaches beyond the detection of physical maladies such as Tay–Sachs disease or brain tumours to identify tendencies to particular types of behaviour or mentality, drawing on recent scientific research that has found, for example, genetic sources for schizophrenia or brain lesions linked to learning disabilities. To be sure, the growth in diagnostic power has far outpaced therapeutic capacity. But never mind: diagnosis has its uses independent of cure. Diagnosis produces information about individuals that can assist life decisions they make for themselves — or that are made for them by others.

Genetic assessments have for some years figured in clinical settings, typically permitting prospective parents to learn the risk of conceiving a child that suffers from a genetic disease or assisting the physician in identifying the physical cause of a patient's malady. However, the broadening powers of neurophysiological and genetic tests are making them evermore appealing as devices to screen individuals with benefit, it is said enthusiastically, not only to themselves but to society. The National Institute of Mental Health has expressed a commonplace expectation: "Pre-symptomatic detection of psychiatric disease will be routine. Subjects at risk for alcoholism, schizophrenia, or depression may be identifiable well before the onset of clinical symptoms" (pp. 5–6). Families and physicians will thus be better prepared to take preventive action or apply therapeutic measures.

Diagnosis is similarly touted for use elsewhere in society. In the schools, it will assist teachers in dealing with troublesome children; in the courts, help specify the degree of a defendant's mental capacity; in the insurance world, aid in the determination of a client's health risk and, hence, premiums; and in the workplace, identify the propensity of workers to fall ill in response to, say, chemicals. According to the *Journal of Occupational Medicine,* diagnostic screening makes good business sense because it can "lead to reduced absenteeism, increased productivity, and decreased expenditures for workers' compensation and group health insurance" (p. 90).

In *Dangerous Diagnostics,* a critical survey and analysis of the diagnostic trend, Nelkin and Tancredi allow that the testing may indeed be valuable — as is, for example, DNA fingerprinting in the courts — but they argue, with arresting persuasiveness, that much of it is alarming. Nelkin, a sociologist at New York University, is an authority on the affairs of science and society. Tancredi directs the Health Law Program at the University of Texas Health Science Center in Houston. Their respective talents and expertise are advantageously joined in this book, which they wrote to stimulate debate about "the potential uses and abuses" of the emerging biological tests and as a kind of technology assessment addressed to their inherent social and political implications (p.ix).

Among the strengths of Nelkin and Tancredi's treatment is their insistence that the danger in diagnostics arises not so much in any evil intent as in the way that institutional contexts, and the values inherent in them, encourage the assessments to be used — and abused. A rapidly growing diagnostics industry presses the tests upon the world ("The future lies in genetic tendencies", an industrial biotechnologist has declared – p. 5). In the courts, reliance on 'hard' biological evidence of mental condition may improve the efficiency and reduce the costs of the judicial process; it can also exclude traditional psychiatric testimony that places the mental state of defendants, to their advantage, in a broader setting. Diagnostic screening in the workplace may improve productivity and decrease liability; it also shifts responsibility for workplace hazards from the company to the employee. Screening may better reveal an individual's risk of disease; but it enables health-care providers and

NEW BOOKS FROM WILEY

Ozone Depletion: Health and Environmental Consequences

Edited by R RUSSELL JONES, St John's Hospital for Diseases of the Skin, London, and T WIGLEY, Climatic Research Unit, University of East Anglia, Norwich, UK

The contents of this book are based on a major international conference which brought together scientific experts in the different areas of ozone depletion, as well as key political figures The book represents a unique compilation of the most recent data on stratospheric ozone depletion with important contributions on global warming Included in the book is a discussion on the chemical processes which have contributed to ozone loss, the basis of future projections and the health and environmental consequences which are likely to result

New Books

Chemical Engineering Design Project, A Case Study Approach,
Martyn S. Ray and **David W. Johnston**
Volume 6 in the series *Topics in Chemical Engineering*
This work is a concise text for final year chemical engineering undergraduates, providing fundamental and practical instruction for the successful completion of a design project
September 1989; 392 pp
2-88124-713-X (hard) $90.00
2-88124-712-1 (soft) $49.00
$39.00 (text)
A Gordon and Breach Book

Combustion: A Study in Theory, Fact and Application
J. Chomiak
Volume 8 in the *Energy and Engineering Science* series
This book provides a broad view of combustion science, written at a level that will be understood by readers who may be specialists in one of the combustion related areas, but who require a knowledge of the subject as a whole.
1989; 400 pp
0-85626-453-9 (hard) $118.00 list / $65 00 individual
0-85626-500-4 (soft) $75.00

EARTH SCIENCES from ELSEVIER

Clays, Muds, and Shales

C.E. Weaver

This book provides a comprehensive and critical summary of clay mineral literature that relates to geology and geologic processes, making it useful both as a reference book for geologists and as a text for the specialist. It is liberally sprinkled with x-ray patterns, chemical analyses, and SEM and TEM pictures, in addition to hundreds of examples.

Asbestos in the Natural Environment

H. Schreier

Examines non-occupational exposure and environmental effects of asbestos relating to animal and plant growth in the natural environment. Given the complexity of the asbestos analysis and the extent of the problem, this book attempts to bring together the multitude of subjects pertaining to asbestos in the natural environment with the aim of contributing to a better understanding of the chemical characteristics of asbestos-rich materials and their effect on plant growth.

1989 xii + 160 pages

Chinese Sedimentary Basins

X. Zhu *(editor)*

Elsevier's new book series *Sedimentary Basins of the World* aims to provide an overview of the geology of sedimentary basins. The books will form a major reference series on basin geology, and should be on the shelves of every earth science library.

This first volume summarizes the geology of Chinese sedimentary basins, their origin, sedimentary history, tectonic evolution and economic potential, presenting much up to date and previously unpublished (outside China) geological and geophysical information from the files of regional surveys and petroleum-research organizations. Invaluable for university courses because of its new perspective of basin analysis, this book will quickly become the definitive source on the subject

1989 xviii + 238 pages

A strange type of addiction

David L. Hull

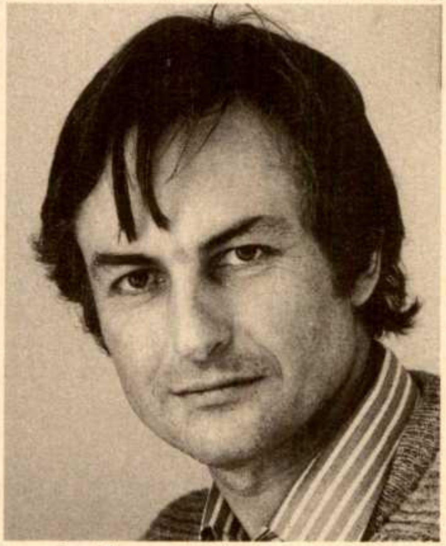
The Selfish Gene, new edition. By Richard Dawkins. *Oxford University Press: 1989. Pp. 352. Hbk £17.50, $22.95; pbk £5.95.*

The Selfish Gene appeared in 1976. Dawkins wrote the book to educate general readers about biological evolution, to prod experts out of their slumbers over the issue of individual selection and to catch the imagination of students. He succeeded on all counts. For this second edition, he has not engaged in rewriting on a large scale. Instead he has added two chapters at the end and interspersed his text with footnotes in which he acknowledges errors, expands on certain points and replies to his critics. The result is a more moderate and conciliatory book than the original. Dawkins has caught our attention. Now he can afford to present his views in more measured terms.

One of the issues that has fascinated Dawkins is exactly how nice we can be given the constraints placed on us by biological evolution, in particular the 'selfishness' of genes. He is not impressed by objections that genes can no more be selfish or unselfish than atoms can be jealous. Scientists have always borrowed words from ordinary language and transformed them into technical scientific terms. If Newton could use the Latin equivalent to 'force' to characterize mass, and quantum physicists can talk about a subatomic particle having 'charm', then biologists are justified in turning 'selfishness' into a technical term as well. Unfortunately, some choices can lead to misunderstandings — the selfishness of genes in the technical sense has consequences for the selfishness of organisms in a more ordinary sense, and the two are easily confused.

Dawkins is swayed more by objections that turn on the social implications of his way of expressing himself. He began working on *The Selfish Gene* in 1972 when power-cuts resulting from industrial strife forced him to interrupt his laboratory research. At the time the behaviour of the working classes in Britain seemed to offer increasingly good examples of selfish short-sightedness. But times have changed: "Now that Britain has a government of the new right, which has elevated meanness and selfishness to the status of ideology, my words seem to have acquired a kind of nastiness by association that I regret" (p. 268). He also regrets his overly cynical and selfish view of life expressed in his chapter on the battle of the sexes, but at the time he felt the need to counteract the Pollyannaish view then prevalent of the relation between the sexes.

In the original book, Dawkins acknowledged that a "human society based simply on the gene's law of universal ruthless selfishness would be a very nasty society in which to live". In part he intended to warn us that if we want, as he does, to "build a society in which individuals cooperate generously and unselfishly towards a common good, you can expect little help from biological nature" (p. 3). Our only hope for a better society is to understand our biological make-up and to counteract it. As surprising as it might sound coming from someone who has so strongly emphasized the role of genes in biological evolution, Dawkins nevertheless insists that "Darwinism is too big a theory to be confined to the narrow context of the gene" (p. 191). Genes function as the replicators in biological evolution while memes serve this same function in cultural evolution.



Dawkins — catching our attention.

Early darwinians such as Huxley presented their contemporaries with the choice of either darwinism or miracles. Dawkins seems to be presented with a comparable dilemma — either genetic determinism or free will. He insists that he was not and never has been a genetic determinist. Genes exert the same sort of statistical influence on behaviour as on other phenotypic traits. Genes are necessary. They are never sufficient. The influence of genes can be "modified, overridden or reversed by other influences" (p. 331). These other influences are to be found in our environment, especially in our society. "We, that is our brains, are separate and independent enough from our genes to rebel against them" (p. 332). The crucial issue is our power to influence which memes come to reside in our brains. Memetic determinism is no less deterministic than genetic determinism. We can rebel against our genes, but can we rebel against our memes? Science is one way. If science is anything, it is a method that can force us to change even our most cherished memes.

The two additional chapters added by Dawkins are entitled "Nice Guys Finish First" and "The Long Reach of the Gene". The first corrects and expands upon his earlier discussion of evolutionarily stable strategies. If one looks at simple versions of such game-theoretical problems as the Prisoners' Dilemma, it is difficult to see how cooperative behaviour can become prevalent. Nice guys cannot win. But in real life organisms play repeated (or iterated) games. Behaviour that has a low payoff if each game is made up of new players can become prevalent if successive games are played with the same contestants. In iterated games it turns out that the nastier strategies rarely prevail — and selection is inherently an iterated game. Thus, Dawkins concludes that "even with selfish genes at the helm, nice guys can finish first" (p. 223). But notice that genes are still at the helm.

The other new chapter is not concerned with who is nasty and who is nice but with the basic structure of selection processes themselves. For all the modifications that Dawkins has introduced into his theory, he still argues for the primacy of genes, but he now sees more clearly in what ways they are more primary than organisms. In selection processes entities must replicate themselves. They must interact causally with their environments in such a way that replication is differential. Differential replication in the absence of such environmental interaction is drift, not selection. Dawkins terms the entities that perform the first function "replicators". According to him, genes are the sole replicators in biological evolution. Replicators can interact directly with their environments or produce more inclusive entities (vehicles) that perform this function for them.

One of the reasons why Dawkins wrote *The Selfish Gene* was to combat the alacrity with which so many ethologists explained certain behaviours in terms of group selection. "We can now see that the organism and the group of organisms are true rivals for the vehicle role in the story, but neither of them is even a *candidate* for the replicator role" (p. 254). Organisms and even certain sorts of colonies can function in selection processes — as vehicles, not replicators. Dawkins is a genic replicationist, not a genic selectionist.

The part of the second edition that I found most valuable is Dawkins's reworking of the foundations of our understanding of the evolutionary process. All that is necessary for selection to occur is that genes have phenotypic effects. But, in point of fact, genes are organized into genomes, they gang up in cells, cells gang up into multicellular organisms and some organisms gang up in colonies. If discrete,

Alternative Life-History Styles of Animals

edited by **Michael N. Bruton**

PERSPECTIVES IN VERTEBRATE SCIENCE 6

Fresh and sometimes controversial insights are provided on the consequences of bifurcation for epigenesis and evolution, and a suggestion is made that new paradigms are emerging which emphasize the harmonious self-organization of natural systems (cells, organisms, communities and ecosystems).

1989, 624 pp. ISBN 90-6193-662-4
Hardbound Dfl. 400.00/£129.00/US$215.00

Inland Waters of Southern Africa: An Ecological Perspective

by **B. R. Allanson, R. C. Hart, J. H. O'Keeffe** and **R. D. Robarts**

MONOGRAPHIAE BIOLOGICAE 64

The book commences with a scene-setting review (in four chapters) of the relevant aspects of the sub-continent, followed by a discussion of the river and its catchment, floodplains and wetlands, and of natural and man-made lakes. The various data are drawn together in the last section, which is devoted to a synthesis and the implications of the findings. Extensive references and index complete the work.

1989, 464 pp. ISBN 0-7923-0266-4
Hardbound Dfl. 300.00/£100.00/US$159.00

Acid Waters in Wales

by **R. W. Edwards, A. S. Gee** and **J. H. Stoner**

MONOGRAPHIAE BIOLOGICAE 66

The book deals with: Evidence for Acidification (Paleo-ecological and contemporary); Causes of Acidification; Effects of Acidification (on ecology, fisheries and water-supply); Catchment studies (including hydrochemical and biological modelling) and Potential Solutions. Chapters on Ecotoxicological Studies and the Chemistry of Aluminium are included.

1990 ISBN 0-7923-0493-4
Hardbound price to be announced

Evolution of Laurussia

A Study in Late Palaeozoic Plate Tectonics

by **Peter A. Ziegler**

This volume provides earth scientists with an overview of the late Palaeozoic evolution of North America, Europe, the Arctic and North Africa in a plate tectonic framework.

individually purposeful vehicles are not necessary for selection, why are there so many of them? And why do multicellular organisms adopt a 'bottlenecked' life cycle?

The crucial distinction for Dawkins is not between sexual and asexual reproduction, but between those organisms that periodically go through cellular bottlenecks and those that do not. In the second case, no difference exists between growth and reproduction. Mutated cells find themselves clumped with distantly related cells that retain the original genetic make-up. But organisms that go through single-celled bottlenecks can go back to the drawing board. Instead of attempting to reorganize an entire organism, all that has to be modified is a single genome. Sequestering certain cells into germ lines facilitates the evolution of complex organisms. This mode of organization seems so advantageous, one wonders why it is not universal. Clonal organisms must be doing something right because they are still with us.

Although Dawkins grants that bare genes are invisible to natural selection, he argues that natural selection acts on genes through differences in their phenotypic effects, and these effects need not stop at the boundaries of our bodies. They extend to all the effects that a gene has on the world, including responses in the behaviour of other organisms. Thus, both Dawkins's book and the responses to it count as part of his extended phenotype. In one place, he describes an adult dunnock feeding a cuckoo chick that it has been tricked into adopting. The dunnock is so much smaller than the cuckoo chick that it must perch on the back of this monstrous foster-child to feed it. Dawkins remarks that German ornithologists refer to such foster-parents as 'addicts' and their cuckoo nestlings as their 'vice'. As I read this description, I pictured him perched atop his theory attempting to feed its gaping mouth. Scientists give every appearance of being addicts, and science is their vice. That is one reason why progress in science is so rapid. I for one have benefited a great deal from Dawkins's addiction. ☐

David L. Hull is in the Department of Philosophy, Northwestern University, Evanston, Illinois 60208, USA.

Facts of life

W. F. Bynum

The Timetables of Science. A Chronology of the Most Important People and Events in the History of Science. By Alexander Hellemans and Bryan Bunch. *Simon & Schuster, New York/Sidgwick & Jackson, London: 1988/89. Pp. 656, $29.95, £19.95.*

Asimov's Chronology of Science and Discovery. By Isaac Asimov. *Harper & Row, New York: 1989. Pp. 707. $29.95, £22.95.*

WHAT are we to make of the almost simultaneous publication of two chronological guides to the history of science and technology, especially when a third — *Breakthroughs: A Chronology of Great Achievements in Science and Mathematics* by Claire L. Parkinson (Mansell, 1985) — has already been remaindered? One conclusion is simply that publishers think such books will sell (despite the remaindered example). More significantly, perhaps, is the fact that scientists do think about the history of their endeavours chronologically. As popularly conceived, scientific knowledge is cumulative, in ways that make it matter that Newton came after Galileo, or Dalton followed Lavoisier. Dates also count in priority disputes, to say nothing of the excuse anniversaries provide for holding jamborees. Who knows, anniversarial studies may even be recognized soon as an important branch of the history of science.

Some of the attractions and pitfalls of this emerging discipline are amply illustrated by the two books under review. Asimov's is the easier to read, because he writes short, discursive essays, mostly of around 200 words, for most of the discoveries or inventions covered. There is something for every year since 1793 and for most years from about 1600. It all becomes rather formulaic: 1902 and 1970 were good years, with eleven entries each, whereas 1958 and 1928 were rather ordinary, with only five. Fleming's discovery of penicillin gets about as much space as Marguerite Perey's discovery of francium, Diderot's *Encyclopédie* about as much as the fifth satellite of Jupiter (Amalthea).

Asimov ends with the greenhouse effect, 4,001,988 years after his first entry, on bipedality, thereby giving a symmetry to the volume — if the first process had not occurred, neither would the last. In between there is much to admire but also everything to take on trust. As befits the author of 425 other books, Asimov has eschewed preface, acknowledgements, references or bibliography. The only personal touch is a dedication.

Hellemans and Bunch (both of whom are science editors) don't tell us where they got their information from either, although in the preface they acknowledge help and provide the useful information that they "have relied upon the consensus of many historians of science whose works we consulted to help locate the events as closely as possible". They record about 10,000 separate items, ranging from a birth or a death to a publication, experiment or invention. Throughout, a 'general' column locates the ordinary events of history (beginning of the English Civil War) or 'non-scientific' aspects of their story (publication of Freud's *Jokes and Their Relation to the Unconscious*, introduction of Oreo cookies by the National Biscuit Company). Their timespan is shorter than Asimov's: they also end in 1988 but don't begin until 2,400,000 BC. The spare, atomistic approach to separate bits of information makes the book impossible simply to read. But a series of nine overviews (for example "Science after World War II") and more than 100 short essays provide some social and intellectual context for entries such as "A. Meissner invents a radio transmitter with vacuum tubes" (1913), "Permanent press clothing is introduced" (1964) or "Ernst Chladni invents the euphonium, a musical instrument in the tuba family" (1789).

The assiduous reader of Asimov would not have picked up any of these latter facts. For Asimov, the key dates for the radio are 1895 (radio antennae), 1901 (Marconi's sending of radio signals from England to Newfoundland), 1904 (J.A. Fleming's rectifier), 1906 (R.A. Fessenden's work on amplitude modulation), 1916 (E.H. Armstrong's superheterodyne receiver), 1939 (Armstrong's perfection of frequency modulation), 1948 (transistors) and 1954 (improvements in the transistor). For Hellemans and Bunch, there are at least 21 key moments, in addition to Meissner's work. For them, the radio antenna did not properly appear until 1905, Armstrong's superheterodyne receiver came in 1918 and Armstrong perfected frequency modulation radio in 1933. These authors agree with Asimov on the other dates, they also add a number of other moments in the history of radio.

Discrepancies also emerge in cross-checking through a year rather than a subject. Take 1922, for instance. Asimov writes of Leonard Woolley's excavation of Ur (dated to 1918 in Hellemans and Bunch, where his name is spelled Wooley); Howard Carter's discovery of Tutankhamen's tomb (confirmed by H and B); Herbert Evans's work on what became known as vitamin E (confirmed by H and B, although with the addition of K. J. Scott); Evans's research on growth hormone (not mentioned at all in H and B); Alexander Fleming's isolation of lysozyme (dated to 1921 in H and B); Oparin's work on the origin of life (under 1936 in H and B); experiments of J. Erlanger and H.S. Glasser on nerve conduction (recorded by H and B under 1944, when the Nobel prize was awarded); and A.A. Friedmann's work on the expanding Universe (confirmed by H and B).

Who would want to be an anniversarial scientist when there is so much uncertainty about the facts of history, to say nothing of their interpretation? Not I, which is why I have steadfastly refused to adjudicate between Asimov and Hellemans and Bunch. It would, after all, simply be my reference books against theirs, and since they have declined to reveal theirs, it would be an unequal contest. I have reason to believe, however, that Leonard Woolley spelled his name thus. ☐

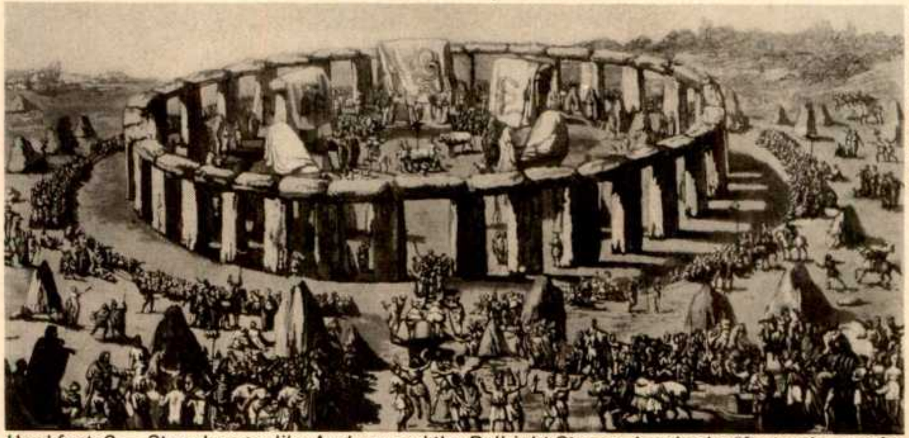
Of thoughts past

Graham Ritchie

Ancient Britons and the Antiquarian Imagination: Ideas from the Renaissance to the Regency. By Stuart Piggott. *Thames & Hudson: 1989. Pp. 175. £14.95, $19.95.*

As excavation techniques extend the range of what can be recovered, and theoretical considerations crowd into university curricula, archaeology increasingly turns to science. How important it is, therefore, that in the history of ideas about early British antiquity we should be aware of the attitudes of early scholars and have an appreciation of the framework within which their thinking took place. Stuart Piggott's perceptive exploration of antiquarian ideas draws together many strands of research to create a fascinating picture of the intellectual worlds of well-known figures such as Aubrey and Stukeley, and at the same time introduces many lesser known writers from the late sixteenth to the early nineteenth centuries.



Mary Evans Picture Library

Hard facts? — Stonehenge, like Avebury and the Rollright Stones, inspired a "fantastic past for ancient Britain, dominated by fictitious Druids".

The past must be understood within the intellectual constructs of the time, and thus we are not introduced to approaches to prehistory — for the term prehistoric was first used by Daniel Wilson in 1851 — but to a world for which the chronology of early times was outlined in the Old Testament. The early antiquaries are to be seen as individuals undertaking research within their own views of the world. It is a measure of Piggott's success that within this rigorous approach the reader is so pleasurably taken on a voyage of exploration through the worlds of the computation of Biblical chronologies, ancient giants and what happened after the Flood.

The Indians and Eskimos — even a Brazilian king — who were transported from the New World to be paraded before the European public in the course of the sixteenth century had a considerable effect on antiquarian approaches and on the way in which early Britons were depicted. It is startling to realize that at least a thousand Red Indians were brought back to Europe by early voyagers and that Frobisher brought Eskimos back from his expeditions to South Baffin Island in 1576–77. Early antiquaries drew comparisons between aspects of American Indian and Eskimo characteristics and those of the ancient Britons. Ethnographical illustration had a great deal of influence on the way that early man was depicted, and Piggott has assembled an unusual series of illustrations of Eskimos, Britons and, most enchanting, Picts and other North British tribesmen.

The fieldwork and recording of monuments by John Aubrey and Edward Lhuyd are set within the context of the day. Our current understanding of monuments such as Stonehenge, Avebury and the Rollright Stones begins with observations made three centuries ago. Thus William Stukeley is seen on the one hand "as a field archaeologist of great distinction" and on the other as the man who misled generations "as the inventor and propagator of a fantastic past for ancient Britain, dominated by fictitious Druids" (p. 122). Stukeley's fieldwork at Avebury and Stonehenge is the earliest detailed recording of field monuments; between 1719 and 1724 he spent up to two months at a time surveying them using a theodolite, and making notes and drawings. In a way that we think of as 'modern', Stukeley's concern was to put on record monuments at risk from agricultural and building developments. ▶

Piggott sets in context the decline in scientific endeavour in the decades following 1700, and leads us through to the campaigns of barrow-digging in Wiltshire a century later. Some archaeologists today belong to the traditions formulated at that time, and I can feel much sympathy for the "young antiquary, who, from practice, can open a barrow as nicely as you could cut up an apple pye; and from his description, it is done much after the same manner" (p. 156). Archaeologists need to understand how our attitudes to the past have been moulded.

In this volume Stuart Piggott draws together themes that he has discussed in his studies of the Druids, in his collected essays on antiquarianism, *Ruins in a Landscape*, and in his biography of William Stukeley. Here they are put within an historical and cultural setting that is both accessible and authoritative. ☐

Complex stability

Paul Colinvaux

Thinking Green: An Anthology of Essential Ecological Writing. Edited by Michael Allaby. *Barrie & Jenkins, London: 1989. Pp.260. £14.95.*

In its issue of 23 September 1989, *The Economist* carried a review of the economies of Third World countries. The conclusion was that whether these economies caused disastrous poverty, or wealth like the dragons of Asia, depended only on whether the governments are good or bad, and no mention was made of possible limits to growth on a finite Earth. Writers in the environmentalist 1970s saw things differently. Their concern was for the miserable social consequences of human numbers rising beyond some critical density, or for the fouling of the human nest by industry. Both views are surely right.

But in their anxiety to tell their dreadful truths, the 'green' writers made what Sherlock Holmes called "the capital mistake" of reasoning beyond their data. Their predictions of famines and shortages and limits and catastrophes were not warranted by what we knew. Readers of *The Economist* can therefore ignore them, even as green philosophies begin to mould the politics of the industrial states.

Thinking Green is a first-class anthology of extracts from the sacred texts of the greens, 45 short essays in all. *Silent Spring*, *The Commons*, Malthus, *The Population Bomb* and *Spaceship Earth*; all are here, together with their many supporters and a tiny few of their opponents. The extracts are short, mercifully so in the case of the wearisome establishment rewrites of such documents as *The Brandt Report*, and of *Global 2000* and *Blueprint for Survival*. But the propagandists themselves are generally a very good read. Rachel Carson is superb, standing out even among essays that include Charles Dickens writing on 'Coketown'. This is a book around which to build a seminar for our times.

But the seminar will have to acknowledge much error on the path to truth. Green thinking is riven by longing for a superorganismic Earth that never was. Green writers declared that the complex was stable and the simple not. Almost no modern ecologist will accept this; mathematics, empirical data and the process of natural selection are all against it. Yet the mystical belief in an organic nature not to be trifled with lingers on. *Global 2000* had in its opening sentence the idiot assertion that the coming world would be "less stable ecologically", and this was 6 years after Robert May's demonstration of the falseness of complexity–stability theory. The latest reincarnation of a superorganismic Earth is complete with a name from the myths whence it came, 'Gaia', and is allotted two extracts.

The Mansell Collection

Thomas Malthus — original thinker.

The central catch phrase of Malthus, that food supplies grow arithmetrically whereas populations grow geometrically, has proved meaningless. Food supplies have often been increased exponentially for prolonged periods. And human beings do not breed like animals, but do so under conscious parental choice subtly affected by cultural values. Malthus himself knew this, and in the extract from his *Essay on Population* declaims against the "viciousness" that follows times when men elect not to marry.

Mercifully, green propagandists now also realize that they were grievously misled by those who threatened us with a loss of atmosphere as the wages of pollution, so that none of the extracts in the book include ponderings about our running out of oxygen because of the poisoning of plants in the sea. The editor must have chosen his material with care.

With these essential criticisms in the open, the core of *Thinking Green* describes the true dilemmas of our times. The good life requires access to a diverse nature, people in tolerable densities and freedom of choice, qualities that are not so easily provided as is the 'wealth' that economists measure.

The numbers of people can be contained, if we have the patience of generations, as we must. The curse of excessive families is a cultural curse, not a biological one. We do act to regulate our reproduction, even the poorest of us when settled in stable cultures. If we think with the green writers, as I do, that the sooner we bring the numbers down the better, then there is an easy way. Liberate women completely, in culture after culture, so that female lives are fully equal in opportunity to those of men. Can anyone doubt that women so liberated would, on the average, decide to have fewer children?

Some environmental abuses are solvable by law, although neither the laws nor the methods of enforcement have yet been devised. The tragedy of the commons is being played out in the world oceans as Asian ships with 30-mile nets strip out all large living things; world law and warships could correct this, as they did for a different form of piracy long ago.

The misery of peasants in lands once parts of Spanish and British empires comes in part because productive land was taken from them to grow cash crops to support Spanish and English gentry, a way of life that is retained by their local, gentrified successors. In the English heartland of the industrial revolution, subsidized industry — posing as farming — tears down the beauty, albeit artificial, of the countryside to grow sugar beet that no one needs. And the tragedy of sugar production is but a repertory-company version of the grander tragedy being acted out in the Amazon basin.

Politics and law are the only tools that can be used to redress these assaults on decent living. So the greens turn political. Alas they also turn socialist, despite the warnings from the Soviet Union and military dictatorships alike that state control does not lead to the preservation of land or biological diversity. But green thinking is inside politics to stay and the greens may yet be the law-givers. ☐

THE CELL CYCLE

Edited by

Robert Brooks, Peter Fantes, Tim Hunt, Denys Wheatley

Journal of Cell Science Supplement 12 Winter 1989

Casebound, approx 300pp. $60 (£40) ISBN 0 948601 23 X

Contents:

Maturation promoting factor, Histone H1 kinase and the timing of mitosis.
Reports on yeast and higher eukaryote cycles from Nurse, Beach, Hyams, Reed, Doree, Maller and Co-workers.

The role of cyclin synthesis and destruction in the cell cycle.
Reports from the Murray, Hunt, Whitaker, Cross and Karsenti laboratories.

The role of DNA damage and DNA synthesis in the control of the cell cycle.
Reports from the Hartwell, Newport, Stillman, Roberts, Laskey and Hutchison groups.

Chromosomes, Centrosomes, Centromeres and Kinetochores.
Reports from Yanagida, Bloom, Hurt, Sluder and Glover

The Cell Cycle is the most up to date analysis of new data and ideas on cell cycle regulation by most of the leading researchers in this rapidly moving and important field

This indexed volume is based on the successful British Society for Cell Biology international meeting held in April 1989 at St Andrews, Scotland.

Warming up the Cold War

Daniel S. Greenberg

Techno-Diplomacy: US–Soviet Confrontations in Science and Technology. By Glenn E. Schweitzer. *Plenum: 1989. Pp.320. $22.95.*

EARLY in the Cold War, Glenn Schweitzer went to Moscow as the scientific officer at the US embassy. Ever since then he has been deeply involved in one of the most perplexing and disputed aspects of the rivalry between the superpowers — their relations in science and technology, which have been maintained to some degree even during the most uneasy periods of the past 30 years.

To the Reagan administration, visiting Soviet scientists were spies, and research in the Soviet Union was too backward to warrant the interest of US scientists. The Reaganites also rejected as infantile the hope that contact with science in the United States would soften Soviet ideology and promote reforms in harmony with Western interests. Schweitzer, who is now staff director for Soviet and Eastern European Affairs at the National Academy of Sciences, makes the contrary case. The issue of 'warmer' or 'cooler' research relations has at present been rendered moot by the glow of *glasnost* but, as Schweitzer points out, the pendulum has swung many times in the post-war years, and may yet swing again. In brief, he makes three points. First, that scientific exchanges are a poor way of collecting strategically valuable research data, and therefore should not be curtailed because of fears of espionage; second, that although Soviet science and technology lag in many fields, other areas are so advanced that US self-interest dictates collaboration with Soviet researchers; and third, that Soviet scientific and technical contacts have helped "blunt the edge of the US–USSR military confrontation", to which, intriguingly, is added the remark that "in Washington, their importance as a rudder of political stability in the rough turbulence of US–Soviet relations has yet to be adequately recognized".

The book contains an odd mixture of officialese and platitudes ("Capabilities in science and engineering spring from a nation's educational system") and fascinating, but often all-too-brief accounts of Schweitzer's personal experience of Soviet science, technology and higher education. For instance, referring to the academic process of thesis defence, he writes: "I have attended some of these sessions; sometimes they are filled with scientific controversy, while on other occasions they seem almost *pro forma* in satisfying an academic requirement". And that's it. Elsewhere, he expresses himself forcefully as when he assails one of the ideological hatchet men of the Reagan era, Richard Perle, for his opposition to Soviet–US scientific relations.

There is no indulgence in romanticism about the brotherhood of science to be found here: for example, "Tourism sometimes becomes a principal motivation for American scientists to participate in exchanges. . . . The ballet and the monastery visits can set the timetable". Likewise, a trip to the West is coveted by Soviet scientists because it gives them the opportunity for a shopping spree. Nor does Schweitzer dispute the contention that the Soviets prey upon Western science and technology to redress their own deficiencies in research. He insists, however, that although Western technology has been useful in some instances, it is not the backbone of the Soviet Union's formidable military power. Furthermore, he points out that technologies that originate in the civilian sector — semiconductors, for example — are increasingly vital to military systems, and are increasingly available on world markets.

Throughout, the weight of the argument is that the strategic risks of scientific amity have been exaggerated while the benefits, scientific and political, have been obscured by right-wing misrepresentations. Along the way, Schweitzer challenges the conventional grumping about Soviet visits to US research facilities, pointing out that exchanges are not an easy way of forging ahead in science. He was formerly director of a laboratory of the Environmental Protection Agency, and notes that he "led many attempts to transfer scientific techniques from our institution to others. . . . We had very advanced techniques, the other laboratories needed them to comply with environmental regulations, and we were eager to facilitate the technology transfer". Nonetheless, bureaucratic inertia and differences in equipment and training requirements meant the process was a time-consuming and difficult one.

As I have mentioned, Schweitzer credits Soviet–US scientific relations with an important role in getting the two countries safely through the Cold War. He suggests that the Soviet Union's scientific window on the West contributed to the country's astonishing ideological turnabout by vividly showing up that country's scientific and technological backwardness. And, on behalf of US interests, he pleads for even closer ties amid the turbulence and uncertainties that currently afflict the Soviet Union.

"Let us hope", he writes, "that our two countries are rapidly emerging from the adolescence of scientific nationalism . . . . Most importantly, American scientists have known and respected for many years Soviet scientific colleagues who are now members of Gorbachev's brain trust and who fully appreciate the need to redirect the Soviet scientific enterprise toward peaceful purposes. The likelihood of their doing so depends to a large extent on the US response to the new opportunities for relaxation of military tensions and for scientific cooperation".

This, he concludes, "is the challenge of techno-diplomacy". □

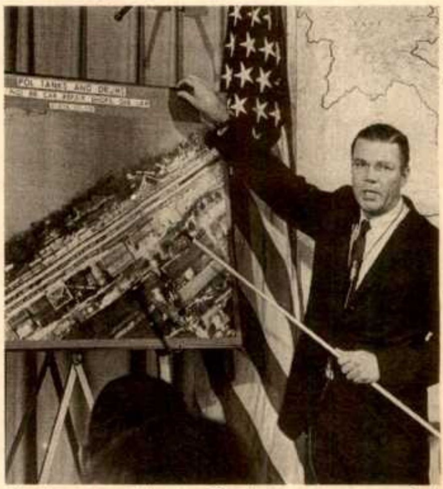
Risky business

Lawrence Freedman

Defending Deterrence: Managing the ABM Treaty Regime into the 21st Century. Edited by Antonia H. Chayes and Paul Doty. *Pergamon–Brassey's, McLean, Virginia: 1989. Pp.286. $32, £20.*

THE 1972 Anti-Ballistic Missile (ABM) Treaty remains one of the most solid achievements of arms control. It was a product of the US–Soviet detente of the early 1970s which came to be associated, eventually, to his embarrassment, with the name of Henry Kissinger. The United States was suffering from the trauma of the Vietnam war and the Soviet Union appeared to be ascendant. Kissinger's hope was to declare a stalemate, create a Soviet stake in the *status quo*, and so prevent a more fundamental challenge to Western interests.



Popperfoto

McNamara giving a Pentagon press conference during the Vietnam war, 1960.

The initiative which eventually led to the treaty can be traced back to the ideas associated with Robert McNamara, US Secretary of Defense for much of the 1960s. While Kissinger understood stability largely in terms of a political arrangement with the Soviet Union, of which an arms-control treaty was an important component, McNamara saw it more as a

military arrangement.

During his tenure in office, McNamara had stressed the need for a stable military balance. By this he meant that in a crisis neither side would have any incentive to strike first with nuclear weapons in the hope of denying the opponent a prospect of retaliation. The concept was of mutual assured destruction. Stability was a consequence of a shared vulnerability — when both superpowers might be consumed in a conflagration, neither side would light the touch paper.

Anything that could reduce vulnerability might reduce stability. This included defensive weapons. A 'shield' on its own might seem innocuous — the most moral form of armed force — but it could tilt the balance in a contest between two sides hitherto armed only with swords. During the 1960s the Soviet Union, unconvinced by this notion and anxious to build barriers against all possible attacks against its territory, constructed a first-generation anti-ballistic missile system around Moscow. McNamara did not want to imitate the system because he believed, correctly, that new offensive methods, and in particular multiple warheads, could overwhelm any defensive missiles.

Nonetheless, as he was leaving office he was obliged to authorize the construction of a US ABM system, ostensibly designed to cope with the first Chinese missiles. In 1969 the Nixon administration made this more explicitly anti-Soviet, but faced difficulty in gaining public, scientific and congressional support. The system become dispensable and was sacrificed to achieve the 1972 treaty.

Just over ten years after the treaty came into force it was challenged by the Strategic Defense Initiative (SDI), set in motion by President Reagan in 1983. Reagan and his supporters abhorred the idea of mutual vulnerability. It would be better, the president insisted, to "save lives" rather than "avenge" them. He hoped to find means of destroying offensive missiles during the first stages of their flight paths, from boost phase to the re-entry of the nuclear charges into the atmosphere. From early on it was pointed out that such an effort was in direct contradiction to the ABM Treaty. The treaty prohibited not only the deployment, but also the development and testing of all systems other than fixed, land-based interceptor missiles and their associated radars of the sort that had been in place in 1972 and that could not be modernized, albeit within very strict numerical limits (initially 200 and then later 100 interceptors for each side).

Once the president's will was known the initial reaction from the Pentagon was that, should the research appear promising, the ABM Treaty could be dispensed with if necessary. However, instead of mounting such a direct assault on an arms control treaty, at a time when the president was claiming to favour arms control in principle, a more indirect approach was adopted, exploring what might be permitted on generous interpretations of the treaty's provisions. The treaty only covered 'strategic' missiles; might it be possible to develop a system to deal with 'tactical' missiles in Europe? There was overlap between anti-satellite and anti-missile weapons; might the former be used as a cover for the development of the latter? The treaty limited the testing of 'components', but what might be done with sub-components? There was a complicated provision concerning the testing of systems based on 'new physical principles'; despite uncomplicated and apparently unambiguous language to the contrary, could this be construed as allowing the development and testing of anything involving new technologies?

This assault on the treaty was complicated by the Soviet response to the SDI. Instead of simply saying that if it went beyond research it would be prohibited, Soviet spokesmen insisted that even research was not allowed. Later they proposed an extended mutual commitment to staying within the treaty's terms, but by this time the main issue had become the Reagan administration's broad interpretation of the terms. The Soviet position was not helped by doubts over its own compliance. Matters became more complicated with proposals to get out of the impasse by considering agreed experiments that could be undertaken without undermining the treaty completely.

Those who prefer the known strengths of the treaty to the doubtful promise of SDI have thus been forced to pit technicality against legality. The number of people truly competent to do this are few and most of them have contributed to the book under review. All of the main areas of controversy are addressed. The conclusion, not surprising from the book's title, is that the purpose and constraints of the treaty are far clearer than those who have sought to undermine them would have us think. I do not believe that the opposing view could have assembled anything approaching the same weight of argument and expertise, even though it notionally remains that of the Bush administration.

Defending Deterrence is not an easy read, and it would have been refreshing to have had a more critical look at the concept of deterrence which is being defended. But the book is comprehensive, authoritative and lucid. Should negotiations on the future of the treaty gather pace during the coming months it will be hard to find a more useful work of reference; if the two governments decide that it is all too difficult, then Chayes, Doty and their contributors will help explain why. □

John A. Campbell

Benefits and Risks of Knowledge-Based Systems. Report of a Working Party of the Council for Science and Society, chairwoman Margaret Boden. *Oxford University Press: 1989. Pp. 76. Pbk £6.95, $14.95.*

ARTIFICIAL intelligence (AI) is in the news less often now than it was in the early and middle 1980s. At present there is nothing quite like the world-wide interest in the Japanese 'Fifth Generation' plan or in the novelty and first commercial successes of expert systems that produced all the previous attention. But AI research operates rather like a volcano: there is constant activity underground, which becomes visible only during eruptions. It is likely that neural nets will cause the next eruption, and in the not-too-distant future.

Among AI researchers there is the saying "AI exports its successes". What this usually means is that the wider public that makes use of the successes no longer sees them as part of AI (the languages LISP and Prolog are examples). Now expert systems seem to be going in the same direction, like lava that is cooling down into easily-handled pieces of stone.

In some quarters, this comfortable trend towards cooling or domestication is even seen as not being fast enough. In the ESPRIT programme, which is an EEC response to the Fifth Generation plan, calls for proposals for research and development projects regularly contain subject-headings such as "metrication and validation of knowledge-based systems". The implication is that computer programs built around knowledge (essentially the rule-based knowledge that is the distinguishing feature of a typical expert system) should eventually be metricated, validated and domesticated with no more trouble than for book-keeping or ticket-issuing programs.

To do the writers of the ESPRIT material justice, they appreciate that they are expressing a hope rather than a certainty. It is unfortunate that this appreciation is not more widespread, especially among people who use or rely on expert-systems technology. The book reviewed here illustrates some of the issues by highlighting the present limitations of the technology, and makes suggestions about how to deal with them. It is welcome because the suggestions are modest and reasonable — for example, that the systems should be treated not as oracles but as assistants to people performing tasks that require specialized knowledge, and that it should be possible for a user to examine the knowledge represented in them. But there is a risk that the book's modesty and low profile will mean that its arguments go unnoticed. Here is a rare case of a book's packaging being too sober.

The special character of knowledge-based systems (KBS) follows from the fact that knowledge is multi-faceted, open-ended, ambiguous and even scruffy, while the functions and specification of (say) book-keeping programs are not. Admittedly there are areas in which the relevant knowledge is well-behaved and can be given the book-keeping treatment, as in some of the most commercially successful expert systems, but these examples do not mean that all conceivable or desired KBS must have the same properties. One possible criticism of the book is that, by using the terms 'expert system' and 'knowledge-based system' almost interchangeably, it misses a chance to sharpen this point.

Clearly a KBS is founded on knowledge, in whatever representations are available to hold it. An expert system obviously has something to do with expertise, but its original meaning (most of which still survives, particularly in the United States), was tied quite tightly to one single representation for knowledge: *rules*. The most interesting KBS may use rules, but other representations such as frames (collections of information that belong together in some particular context) and inheritance nets (hierarchical structures in which specific items inherit properties from more general items, of which they are particular instances) are used at the same time. This reflects the actual organization of expert knowledge much better, and extends the range of AI applications beyond what was available in the early 1980s. But it also emphasizes the difficulty of predicting all the outcomes and pitfalls when some particular body of knowledge that goes beyond mere rules is represented and used inside a KBS. In this respect, the book gives a fair summary of the issues that deserve to be confronted, even though simple rules are the only examples of knowledge that it uses. To get the most out of the case that it makes, the reader should repeat regularly: "There is more to knowledge than rules".

The fundamental reason for the mixture of cautions and actions that the authors' collective for this book recommends is that a KBS is unlikely to use the same chain of reasoning that a human would use to solve the same problem. The methods of inference in a KBS are local approximations to our own reasoning for parts of problems — sometimes optimistic approximations (for example, the psychological evidence that we do any reasoning with the help of logic as a mathematical logician would describe it is very thin). But there is no general AI method that imitates our perception and treatment of a reasoning problem as a whole. This gives force to the recommendation that a KBS should be used as a human's assistant and not (unless provably domesticated) trusted as an autonomous agent, especially where human life and safety are concerned. An assistant who suggests initiatives should always be capable of explaining them in terms that a human senior partner can understand and accept. This concentrates attention on the ability of a typical KBS to explain its actions, and here there is still plenty of room for improvement. Explanation, or lack of it, is also likely to be the main weakness of neural-net systems, despite their strengths in other respects. Therefore, the book's relevance will not be changed by the arrival of neural nets on the commercial scene, if this indeed causes the next eruption of publicity for AI.

Relevance and reasonableness alone are not enough to make a political impression, alas. Subversion of the established (commercial) order is a better way in 1989. If the author's subversive recommendation that a "human or group of humans ... should take moral and/or legal responsibility for the human consequences of any malfunction" of any KBS does not stir up some debate, then nothing will. ☐

John A. Campbell is in the Department of Computer Science, University College London, Gower Street, London WC1E 6BT, UK.

THE MOTOR THEORY OF LANGUAGE ORIGIN

Robin Allott

How in evolutionary terms did humans acquire language? Language cannot have sprung suddenly into existence; it must have had a precursor. The motor theory is that the precursor was the motor control system, the complex organisation of the brain for movement. The book brings together evidence from two major areas of research, linguistics and the neurology of human perception and action.

☆ Cardiopulmonary Resuscitation

edited by **P.J.F. Baskett**
MONOGRAPHS IN ANAESTHESIOLOGY, VOLUME 17
Series Editors: A.R. Hunter *and* T.E.J. Healy

This volume is devoted to Cardiopulmonary Resuscitation It is a fully comprehensive, up to date, well illustrated, reference and text book with contributions from acknowledged experts in the clinical field from both sides of the Atlantic. **Cardiopulmonary Resuscitation** includes sections on the history, epidemiology, infection risks and ethics in resuscitation and deals in depth with training, organisation and clinical practice in basic and advanced life support and the related technology in a wide variety of clinical situations

1989 428 pages, Price Dfl 350.00/US$ 170.75
ISBN 0-444-81051-X

☆ Side Effects of Drugs Annual 13/1989

edited by **M.N.G Dukes *and* L. Beeley**

Once again the vast amount of data on adverse drug reactions appearing annually in the world literature has been critically reviewed by the expert team of authors and editors working on the series, and the book once more provides a complete overview of all known side effects of drugs, both major and obscure.
The 'Special Reviews' section gives special attention to up-to-date topics such as: Medicolegal aspects of the benzodiazepines, New drugs and old principles - the flood of new and potent antimicrobials continues, Zidovudine (AZT); Lipid-lowering drugs - a call for caution, MAO inhibitors: which foods to avoid, what to tell patients

1989 500 pages, Price. US $134.25/Dfl 275.00
ISBN 0-444-81091-9

☆ Pharmacological and Chemical Synonyms
9th Edition

E.E.J. Marler (compilor)

This is the latest edition of the world-famous listing of pharmaceutical and chemical synonyms, including pesticides, which was first compiled in 1956
Marler's 'Pharmacological and Chemical Synonyms' has become widely accepted as the major *international* compilation of synonyms (approx. 50,000) of main substance names (approx 10,000) used in the pharmacological and chemical literature. The alphabetical listing is extensively and consistently cross-referenced.
For people working in the field of pharmacology, pharmaceutics and toxicology, as well as for medical editors and drug regulatory officers, this work will prove to be an indispensable source of information

1990 500 pages, Price US $170.70/Dfl 350.00
ISBN 0-444-90487-5

☆ Developments in Industrial Microbiology, Volume 30

G.E. Pierce (editor)
(Journal of Industrial Microbiology, Supplement 4)

The proceedings of the Society for Industrial Microbiology's general meetings are published annually, as a supplement to the **Journal of Industrial Microbiology**, in 'Developments in Industrial Microbiology' - a volume with worldwide distribution. The sections titles in volume 30 are: The Genetics of Anaerobes, Attacking AIDS. Diagnosis, Drugs, and Vaccines; The Application of Immobilization Technology to the Pharmaceutical Industry, Secondary Metabolism/Biocatalysis Reactions of Use in Synthetic Chemistry, Plant Molecular Biology in Agriculture, Antibiotics; Miscellaneous Section.

1989 318 pages, US $97.50/Dfl 200.00
ISSN 0169-4146

Books are available to non-subscribers at the prices given Members of the Society for Industrial Microbiology should apply directly to the Society.

☆ The Biological Basis of Radiotherapy
Second Edition

edited by **G.G. Steel, G.E. Adams *and* A. Horwich**

Radiotherapy itself has expanded in scope, to encompass advanced technological developments in physics, new concepts in biology and increased complexity in patient management For the young clinician entering the specialty, it is particularly important that full advantage is taken of the opportunities to innovate and to maintain an awareness of developments in science that seem likely to impinge on the field.
This excellent volume will certainly make an important contribution to this awareness, whilst refreshing senior clinicians in established practice.

1989 336 pages
(Hardback) Price: Dfl. 360.00/US$ 175.50
ISBN 0-444-81099-4
(Paperback) Price: Dfl. 140.00/US$ 68.25
ISBN 0-444-81187-7

☆ Relief of Intractable Pain,
4th Revised Edition

edited by **M. Swerdlow *and* J.E. Charlton**
MONOGRAPHS IN ANAESTHESIOLOGY, VOLUME 18
Series Editors: A.R. Hunter *and* T.E.J. Healy

This book, the fourth edition of this monograph, not only describes the current practice of the management of chronic pain, but also attempts to evaluate critically the results obtained by the various modalities of treatment. There is a good balance between the basic science background and the clinical skills required for the optimal treatment of chronic pain
Clinicians who are devoted to the concept that patients need and deserve the most up-to-date care available for the amelioration of their pain problem will certainly find this book as enlightening and informative as its predecessors, if not moreso.

1989 382 pages, Price Dfl 345.00/US$ 168.25
ISBN 0-444-81094-3

☆ Pulmonary circulation - advances and controversies

edited by **C.A. Wagenvoort *and* H. Denolin**

This book focuses on a number of topics within the field of pulmonary circulation in which there have been recent advances or important developments, or in which controversial issues are at stake.
It will no doubt serve not only as an up-to-date source of information but also as a stimulus for further research to cardiothoracic surgeons, paediatricians, anaesthesiologists, intensive care physicians and pathologists, as well as cardiologists and pulmonologists

1989 288 pages, Price. Dfl 285.00/US$ 139.00
ISBN 0-444-81072-2

Reader Service No 31

GUIDE TO AUTHORS

Please follow these guidelines so that your manuscript may be handled expeditiously

Nature is an international journal covering all the sciences Contributors should therefore bear in mind those readers for whom English is a second language and those who work in other fields Please write clearly and simply, avoiding unnecessary technical terminology *Nature*'s staff will edit manuscripts to those ends if necessary Contributors should check their proofs carefully

Because of the competition for space, many of the papers submitted for publication cannot be accepted For this reason, and because brevity is a great assistance to readers, papers should be as brief as is consistent with intelligibility Please note that one printed page of *Nature*, without diagrams or other interruptions of the text, has fewer than 1,300 words

CATEGORIES OF PAPER

Review Articles survey recent developments in a field Most are commissioned, but suggestions are welcome in the form of a one-page synopsis addressed to the Reviews Coordinator Length is negotiable in advance but must not exceed six pages of *Nature*

Articles are research reports whose conclusions are of general interest and which are sufficiently rounded to be a substantial advance in understanding They should not have more than 3,000 words of text or more than six display items (figures and tables) and should not occupy more than five pages of *Nature*

Articles should be accompanied by a heading of 50 – 80 words written to advertise their contents in general terms, to which editors will pay particular attention A heading (printed in italic type) is not an abstract and should not usually contain numbers or measurements The study should be introduced in more detail in the first two or three paragraphs, which should also briefly summarize its results and implications

Articles may contain a few subheadings of two or three words The meaning of the text should not depend on the subheadings, whose function is to break up the text and to point to what follows There should be fewer than 50 references

Letters to Nature are short reports of outstanding novel findings whose implications are general and important enough to be of interest to those outside the field Letters should not have more than 1,000 words of text or more than four display items and should not occupy more than two pages of *Nature* The first paragraph should describe, in not more than 150 words, the origins and chief conclusions of the study Letters should not have subheadings or more than 30 references

Commentary articles deal with issues in, or arising from, research that are also of interest to readers outside research Some are commissioned, most are unsolicited They are normally between one and four pages of *Nature* in length

News and Views articles are intended to inform non-specialist readers about a recently published advance Suggestions should be made to the News and Views Editor Illustrations are welcome Proposals for meeting reports should be agreed in advance

Scientific Correspondence is for the discussion of scientific matters, including contributions published in *Nature* Priority is given to contributions of less than 500 words and five references Figures are welcome

GENERAL

All contributions submitted for publication in *Nature* should conform with these rules

Manuscripts should be typed, double-spaced, with a good-quality printer, on one side of the paper only Four copies are required, each accompanied by lettered artwork Four copies of half-tones should be included Reference lists, figure legends and so on should be on separate sheets, all of which should be double-spaced and numbered Copies of relevant manuscripts in press or submitted for publication elsewhere should be included, clearly marked as such Revised and resubmitted manuscripts should also be clearly marked as such and labelled with their reference numbers

Titles should say what the paper is about with the minimum of technical terminology and in fewer than 80 characters Authors should avoid active verbs, numerical values, abbreviations and punctuation and should include one or two key words for indexing purposes

Artwork should be marked individually and clearly with the author's name, figure number and, when known, manuscript reference number Original artwork should be unlettered Ideally, no figure should be larger than 28 by 22 cm Figures with several parts are permitted only if the parts are closely related, either experimentally or logically Suggestions for cover illustrations, with captions, are welcome Original artwork (and one copy of the manuscript) will be returned when a manuscript cannot be published

Colour Artwork. A charge of £500 a page is made for 4-colour figures Inability to meet these costs will not prevent the publication of essential colour figures if the circumstances are explained

Figure legends must not exceed 300 words and ideally should be much shorter, and should use telegraphic form wherever possible The figure should be described first, then, briefly, the method Reference to a method described elsewhere is preferable to a full description Methods should not be described in detail in the text

References should be numbered sequentially as they appear in the text, followed by those in tables and finally those in the figure legends Reference numbers apply only to papers published or in the press, and a different number should be given to each paper cited All other forms of reference (including unrefereed abstracts) should be included in the text as personal communication, manuscript in preparation or preprint (with number and institution where appropriate) Text should not be included in the reference list References should be abbreviated according to the *World List of Scientific Periodicals* (fourth edition, Butterworth, London, 1963 – 65) The first and last page numbers should be cited Reference to books should clearly indicate the publisher and the date and place of publication

Abbreviations, symbols, units and Greek letters should be identified the first time they are used Acronyms should be avoided as much as possible and, when used, defined Editors will shorten words if necessary In case of doubt, SI units should be used

Footnotes should not be used except for changed addresses or to identify the corresponding author if different from the first-named

Acknowledgements should be brief Grant numbers and contribution numbers are not allowed

Submission *All manuscripts may be submitted to either London or Washington They should not be addressed to editors by name Manuscripts or proofs sent by air courier to London should be declared as 'manuscripts' and 'value $5' to prevent the imposition of import duty and value-added tax (VAT)*

AUTHOR INDEX

- (Chaiken, I M *editor*) **341,** 357
- **Bobrow, M** *Book review of* Cystic fibrosis (Goodfellow P *editor*) **341,** 580
  - *Book review of* The fragile X syndrome (Davies, K E *editor*) **341,** 580
- **Boillot, G** Undercrusting by serpentinite beneath rifted margins (*with* Féraud, G Recq, M, Girardeau, J) *Letter to Nature,* **341,** 523
- **Bokvist, K** *See under* Rorsman, P , **341,** 233
- **Bonamo, P M** *See under* Shear, W A , **341,** 527
- **Bonani G** *See under* Broecker, W S **341,** 318
- **Boncinelli, E** *See under* Wilkinson, D G **341,** 405
- **Bonev, B I** *See under* Avanesov G A **341,** 585
- **Bonnard, G** *See under* Gualberto J M **341,** 660
- **Booth, C C** *Book review of* Health for sale Quackery in England 1660-1850 (*by* Porter, R,) **341,** 115
- **Borchers, R R Editor,** Computers in Physics, *Journal review by* Upstill, C **341,** 370
- **Borg, H** *See under* Lundin, R **341,** 609
- **Bornhold, B D** *See under* Prior, D B , **341,** 47
- **Borst, J** *See under* Vroom, T M **341,** 114
  - *See under* Krimpenfort P , **341,** 742
- **Bos, J D** *See under* Vroom T M **341,** 114
- **Bosnes, V** *See under* Brandtzaeg, P , **341,** 113
- **Bosworth, N** Scintillation proximity assay (*with* Towers, P) *Miscellany,* **341,** 167
- **Bourles, D L** Beryllium in marine pore waters geochemical and geochronological implications (*with* Klinkhammer G Campbell, A C, Measures, C I, Brown, E T, Edmond, J M) *Letter to Nature* **341,** 731
- **Bourouis, M** Mutant *Drosophila* embryos in which all cells adopt a neural fate (*with* Heitzler P El Messal, M, Simpson P) *Letter to Nature,* **341,** 442
- **Bowden, R D** *See under* Steudler P A , **341,** 314
- **Bowman, J R** *See under* Cerling, T E **341,** 138
- **Boycheva, V** *See under* Avanesov, G A , **341,** 585
- **Boycott, B B** *See under* Wässle H , **341,** 643
- **Brady, J** *Journal review of* Journal of Insect Behavior (Bell, W J, Payne T L *editors*) **341,** 362
- **Brand, C** *Book review of* Genes culture and personality An empirical approach (*by* Eaves L J, Eysenck H J, Martin, N G) **341,** 29
- **Brandtzaeg, P** Epithelial homing of γδ T cells? (*with* Halstensen, T S Scott H, Sollid L M, Valnes K, Bosnes, V) *Scientific correspondence,* **341,** 113
- **Brendel, V** Too many leucine zippers? (*with* Karlin, S) *Scientific correspondence,* **341,** 574
- **Brenner, M B** *See under* Porcelli, S **341,** 447
- **Brereton, N R** *See under* Zoback M L , **341,** 291
- **Bretscher, M S** Particle migration on cells *Scientific correspondence,* **341,** 491
- **Brin, D** To boldly go , *Correspondence* **341,** 682
- **Britten, K H** *See under* Newsome, W T , **341,** 52
- **Brizuela, L** *See under* McVey, D **341,** 503
- **Brockes, J P** *See under* Ragsdale, C W **341,** 654
- **Brodsky, M B Editor,** Physica C Superconductivity *Journal review by* Ruvalds J **341,** 368
- **Broecker, W S** Routing of meltwater from the Laurentide Ice Sheet during the Younger Dryas cold episode (*with* Kennett J P, Flower B P Teller J T Trumbore S Bonani, G, Wolfli, W) *Letter to Nature* **341,** 318
- **Brown, A C** Tropospheric lifetimes of halogenated anaesthetics (*with* Canosa Mas, C E, Parr A D Pierce, J M T, Wayne R P) *Letter to Nature* **341,** 635
- **Brown, E T** *See under* Bourlés, D L , **341,** 731
- **Brown, H R** Evidence for cleavage of polymer chains by crack propagation (*with* Deline, V R, Green, P F) *Letter to Nature* **341,** 221
- **Brown, J C** *Book review of* The restless Sun (*by* Wentzel D G,) **341,** 580
  - *Book review of* The Sun An introduction (*by* Stix, M,) **341,** 580
- **Bruinsma, R** Thermodynamics What, if anything, is melting?, *News and views,* **341,** 486
- **Brunner, J** *See under* Vestweber D **341,** 205
- **Bryant, P** *Book review of* Autism Explaining the enigma (*by* Frith, U,) **341,** 395
- **Bryndzia, L T** The oxidation state of the Earth s sub oceanic mantle from oxygen thermobarometry of abyssal spinel peridotites (*with* Wood, B J Dick, H J B) *Letter to Nature,* **341,** 526
- **Brzeska, H** *See under* Fukui, Y **341,** 328
- **Buckingham, M** *See under* Sassoon, D , **341,** 303
- **Bucy, R P** Epithelial homing of γδ T cells?, *Scientific correspondence,* **341,** 113

PROTEIN-NUCLEIC ACID INTERACTION

Volume 10 Topics in Molecular and Structural Biology

Edited by W Saenger and U Heinemann

The book contains articles highlighting the rapidly evolving field of protein nucleic acid interactions Individual chapters demonstrate the diversity of biological systems to which protein nucleic recognition is of central importance

There are chapters on the interaction of small proteins with DNA and RNA as well as on chromatin organisation Care has been taken to include accounts of many different experimental approaches to studying the subject All articles are written by scientists actively involved in the research they describe and considered experts in their respective research areas The book is well illustrated and contains extensive bibliographic information to provide easy access to the original literature

July 1989 £40 00 214pp 234 x 156mm 0-333 45321 2

SCRIPPS INSTITUTION OF OCEANOGRAPHY

BIOLOGICAL OCEANOGRAPHY

pplications are invited for an Assistant, Associate or Full Professor/ urator (tenure track or tenured) position in MARINE PLANKTON-LOGY, level and salary (UC pay scale) commensurate with qualifiations and experience At the time of appointment successful andidates must hold a Ph D degree in a biological science, and must ave a demonstrated excellence in independent research

ualifications include research and teaching interests in the ecology nd evolution of planktonic organisms involving field and laboratory ork, the utilization of plankton collections, and preferably but not ecessarily, expertise in the systematics and/or biogeography of one r more diverse and/or abundant planktonic organisms

andidates are expected to conduct an active research program upported by extramural funds, to be involved in graduate teaching nd supervision of graduate students, and to supervise the maintennce, utilization, and expansion of the institution's extensive marine lankton collection Candidates at the associate or full professorial vel must show evidence of a strong research record Assistant level andidates will be evaluated on their potential, from their publication ecord and letters of recommendation, as appropriate to their level of xperience

lease send a letter of application including a description of research nterests, list of publications, resume of teaching experience and terests in plankton collections, and names of at least five references o

Senior Scientists in Biomedical Science — Kanagawa, Japan

We invite applications and/or nominations for the positions of senior scientists of the Institute for Biomedical Science The Institute, now being reorganized, will consist of four divisions and we call candidates for the following three divisions

1. **Division of Molecular and Cell Biology**
2. **Division of Bioengineering and Biomedical Materials**
3. **Division of Artificial Organs and Organ Transplantation**

The Institute is one of the three Centers constituting the parent center, Terumo R & D (Director General Tetsuzo Akutsu, M D, Ph D and 500 researchers) The new R&D building (44,146 sq meter) is under construction and will be open in December, 1989 It is located in the town of Nakai, Kanagawa Prefecture, one-hour drive away from Tokyo The town is situated on one of the best geographical environments to live in Japan with an excellent view of Mt Fuji in the west and Sagami Bay in the south

TERUMO CORPORATION is a leading manufacturer with an extensive product lineup including artificial organs, pharmaceuticals, transfusion and infusion products, medical electronics, labo products and medical disposables Terumo has manufacturing R&D and distribution facilities in Japan, U S A, Belgium and Australia

QUALIFICATIONS include a Ph D, and at least seven-year experience in one of the three above-described specialized areas, and an excellent record of scientific achievement Successful candidates will have a chance to be promoted to the Division Chief, who is expected to have supervisory responsibilities directing junior staff

SALARY will be commensurate with experience and qualifications We offer house accommodation, and benefits package together with the opportunity to work in our newly constructed superb facilities equipped with modern technologies

A letter of application, C V, list of publications, three professional referees, and your portrait should be sent by the end of December 1989 to the following address

Yutaka Tomita, Managing Director,
Technical R & D Division,
Terumo Corporation,
44-1, 2-chome, Hatagaya,
Shibuya-ku, Tokyo 151, Japan
Phone 03(374)8020, Fax 03(374)7493

Applications will be reviewed continuously until suitable candidates are hired Promising candidates will be contacted for further discussions on the terms of employment contract

(W6595)A

TERUMO CORPORATION

Institut fur Genbiologische Forschung Berlin GmbH

POSTDOCTORAL POSITION

for a Biochemist/Molekular Biologist

A postdoctoral research fellow is required to work on a joint programme with the **Schering AG Agrochemical Research** involving the characterization of plant proteinase inhibitors and their genes The Position is available for 2–3 years

Applicants should have experience with modern methods of protein isolation and analysis and a strong background in molecular biology techniques

Please submit a full c v and the names and addresses of two referees to **Prof Dr Lothar Willmitzer, Institut fur Genbiologische Forschung Berlin GmbH, Ihnestrasse 63, 1000 Berlin 33, Fed Rep Germany**

(W6714)A

AGRICULTURAL AND FOOD RESEARCH COUNCIL (AFRC)

HEAD OF AFRC INTERNATIONAL OFFICE

SWINDON **SALARY £17,360 – £22,606**

plus performance related increments to £26,958 – pay award pending

Already providing research to solve some of the UK's most pressing agricultural and food concerns, the AFRC is committed to developing international research cooperation and to increasing its contribution to the needs of the world's developing nations

COULD YOU IMPLEMENT AND DRIVE THE COUNCIL'S INTERNATIONAL POLICY?

- Improving awareness of the AFRC as a major research resource among international agencies and industrial customers in developed and developing countries around the world
- coordinating the marketing of AFRC's expertise and providing a channel of information on international research opportunities
- developing an early intelligence system for overseas research funding opportunities
- contributing to research policy formulation

Encompassing the many demanding aspects of marketing, technical liaison, presentation, contract negotiation, professional collaboration, targeted fund raising and staff management exercised in a research environment, this challenging position requires a diverse range of skills

If you are an innovative thinker, ideally with a background of both international scientific and administrative experience, the capacity to comprehend and interpret scientific information over a wide range of disciplines and the mobility to travel, please contact us Benefits include non-contributory pension scheme, generous annual leave and flexible working hours

Please apply in writing for an application form and further particulars to Manager, Central Office, AFRC, Wiltshire Court, Farnsby Street, Swindon, SN1 5AT

The closing date for receipt of applications is 1st December 1989

The AFRC is an Equal Opportunities Employer (2113)A

AFRC

POSTDOCTORAL FELLOW or RESEARCH ASSISTANT

A three-year appointment is immediately available for an organic chemist with an interest in biology, to work in the new field of catalytic antibodies (abzymes) These molecules are thought to have great potential in stereospecific catalysts The post is funded by Shell Research Ltd, Sittingbourne and will be held jointly in the Departments of Chemistry and Biology (Cancer Research Unit) at the University of York The successful candidate will be expected to show independence of thought and an ability to bridge biology and chemistry If the successful candidate is employed as a research assistant, they would be expected to register for a higher degree Only candidates with at least a 2 i need apply

Salary within the Research and Analogous scales (£9,816 to £12,381 – grade IB, or £10,458 to £16,665 – grade IA)

Informal enquiries to Dr Colin Garner on 0904-432900

Three copies of applications, with full curriculum vitae and naming two referees, should be sent by 5 December 1989 to the Personnel Office, University of York, Heslington, York YO1 5DD Further particulars are available. Please quote advertisement reference number 6/6280 (2077)A

UNIVERSITY OF YORK

UNIVERSITY OF NOTTINGHAM MEDICAL SCHOOL

Depts of Biochemistry and Genetics

POSTDOCTORAL RESEARCH ASSISTANT GRADE 1A

Applications are invited for a post-doctoral research assistant to work with Dr P Jones and Dr J Brookfield on a project funded by the Medical Research Council to study the role of the protein vinculin in actin reorganisation and cell adhesion during Drosophila embryogenesis The appointment is for 3 years on the 1A scale and is available immediately Experience of Drosophila genetics and/or molecular biology techniques would be an advantage, but not essential

Applications with the names and addresses of two referees should be sent to **Dr P Jones, Dept of Biochemistry, University of Nottingham Medical School, Queen's Medical Centre, Nottingham NG7 2UH,** from whom further details may be obtained (tel 0602-709365) (2044)A

UCL

UNIVERSITY COLLEGE LONDON

Department of Biology

TWO APPOINTMENTS IN PLANT PATHOLOGY/MYCOLOGY

1 A post-doctoral research assistant is required immediately to study the morphological and biochemical basis of the resistance of wheat to the fungal pathogen *Fusarium graminearum* Work on the project will be in collaboration with an Agricultural Station in Uruguay and CIMMYT, Mexico Candidates should have good practical experience of general biochemical techniques

The appointment, which is funded by the Overseas Development Administation, is for three years and will be on the RA 1A scale The initial salary will be determined by age and experience and will be up to a maximum of £14,169 + £1,650 London Allowance

2 A post-graduate, who may register for the Ph D degree, is required to investigate the occurrence of moulds and mycotoxins in oilseed rape at harvest, during storage and following conversion into cake Work on the project will be in collaboration with the Overseas Development and Natural Resources Institute and laboratories in Italy and Pakistan Candidates should have some knowledge of the culture and identification of fungi and the quantitative analysis of biologically active compounds

The appointment, which is for three years, is funded by the EEC The successful candidate will be renumerated at the standard SERC studentship rate (currently £4690 + travel allowance)

Further particulars may be obtained from **Dr R N Strange, Department of Biology, Darwin Building, University College London, Gower Street, London WC1E 6BT** to whom applications, including cv and the names and addresses of two referees should be sent (1921)A

FACULTY POSITION IN BIOPHYSICS AT HAVERFORD COLLEGE

The Department of Physics invites applications for a tenure-line assistant professorship in biophysics Applicants must have a Ph D and be strongly motivated toward creative research and undergraduate teaching The successful candidate will assist in developing a new interdisciplinary biophysics program Substantial start up funds for research are available

Haverford is a liberal arts college outside Philadelphia with an international reputation for strong research and instruction in the sciences Please send curriculum vitae, list of publications, a statement of research and teaching interests, and at least three letters of recommendation by 15 January 1990 to **Professor Lyle Roelofs, Department of Physics, Haverford College, Haverford, PA 19041, USA** *An Equal Opportunity/Affirmative Action Employer* Women and minority candidates are particularly encouraged to apply (NW4573)A

Institute of Terrestrial Ecology

INTERNATIONAL PROGRAMME OFFICER

Tropical Soil Biology and Fertility Programme

A Programme Officer is sought to act as co-ordinator of an international programme of research into the biological bases of tropical soil fertility The Programme is sponsored by the International Union of Biological Sciences and UNESCO, but the post is with the Institute of Terrestrial Ecology, Edinburgh

The appointee will develop the conceptual basis of the Tropical Soil Biology and Fertility Programme (TSBF) through literature review, integration of data from TSBF sites and participation in model development He/she will help to organise and co-ordinate activities between Programme Centres throughout the tropics and with the African network The successful candidate will be responsible to Director TSBF

Applicants should have a first or upper second class honours degree with at least two years' relevant post-graduate experience Tropical experience and expertise in modelling will be an asset

The appointment will be for a period of three years, salary will be in the range of **£10,678** to **£14,909** pa or **£13,254** to **£18,864** pa depending upon experience and qualifications, plus relevant foreign allowances The successful candidate will be stationed at either - Nairobi, Kenya with Dr J Ingram, Co-ordinator of African Network, TSBF or Ibadan, Nigeria with Professor M J Swift, Director TSBF Terms include generous holidays and a non-contributory pension scheme

The Institute of Terrestrial Ecology is a component body of the Natural Environment Research Council

Further details and an application form are available from David Tyers, Institute of Terrestrial Ecology, Edinburgh Research Station, Bush Estate, Penicuik, Midlothian, EH26 0QB Tel 031-445-4343 Fax 031-445-3943 Telex 75259 Closing date for receipt of completed application forms is 30th November 1989

UNIVERSITY OF BRITISH COLUMBIA
Department of Microbiology

Molecular Immunologist

The Department of Microbiology, University of British Columbia invites applications from molecular immunologists for an assistant professor level, tenure track position The individual we seek will have a Ph D, postdoctoral experience, a strong research record and show potential for developing an internationally-recognized research program which will complement ongoing programs in immunology, virology and bacterial pathogenesis Salary will be commensurate with qualifications and experience The successful candidate will be expected to participate in the Department's large and expanding Ph D progarm In accordance with Canadian immigration requirements priority will be given to Canadian citizens and permanent residents of Canada Closing date for applications is February 28, 1990 Position will be available July 1, 1990 The position is subject to final budgetary approval

Please send curriculum vitae, a summary of research interests and the names of three referees to **The Head Department of Microbiology, University of British Columbia, #300 6174 University Boulevard, Vancouver, B C V6T 1W5**

The University of British Columbia is committed to the Federal Government's employment equity program and encourages applications from all qualified individuals (NW4517)A

ASSISTANT/ASSOCIATE PROFESSOR DEPARTMENT OF CELL BIOLOGY

The Department of Cell Biology is accepting applicaitons for a tenure-track position at the Assistant or Associate Professor level Applicant must be qualified to teach gross anatomy to medical students Preference will be given to candidates with teaching experience in gross anatomy in addition to research experience Research interests should complement existing research strengths of the department developmental biology, reproductive biology, neurobiology, growth factors

Send curriculum vitae, description of research interests, and the names of three references to **Paula C Hoos, Ph D , Chairperson of Search Committee, Department of Cell Biology, Vanderbilt School of Medicine, Vanderbilt University, Nashville, Tn 37232–2175**

Vanderbilt University Medical Center is an Equal Opportunity, Affirmative Action Employer (NW4565)A

PHOTOSYNTHESIS RESEARCH GROUP

UCL

Post-doctoral Research Associate

An SERC supported post-doctoral position is available for two years from 1st January 1990 for work on the structure and function of photosystem I

The research programme will involve work on the isolation and purification of photosystem I to determine the role of the smaller polypeptides in electron transport and the application of advanced electron paramagnetic resonance spectroscopy to investigate the structure, and electron transfer mechanisms, in the electron acceptor complex

A background in Biochemistry, Biophysics or Physical Chemistry would be appropriate Training will be available for novel techniques

Salary on the RA 1A scale £10,458-£16,665 plus £1,650 London Allowance

Applications including c v and names of 2 referees should be sent to **Prof M C W Evans, Dept of Biology, Darwin Building, University College London, Gower St , London WC1E 6BT, 01-380 7312,** from whom further details may be obtained Equal Opportunities Employer (2107)A

University of Nottingham
Department of Botany

POST-DOCTORAL RESEARCH ASSISTANT IN PLANT PATHOLOGY

Applications are invited for an AFRC funded research post to work on the genetic control of host species specificy in the downy mildew pathogen *Peronospora parasitica* The 3 year project will utilize rapid-cycling *Brassica* lines and tissue culture approaches to produce hybrids between host genotypes which differ in response to defined pathotypes of the fungus The sexual cycle of the fungus will be used to generate progeny in which the segregation of host range genes will be analysed The project will be based in the Plant Pathology laboratory at Nottingham but will also involve collaborative work in tissue culture and with the Institute of Horticultural Research

Applicants should have appropriate research experience in plant pathology, plant breeding, tissue culture, or genetics Knowledge of molecular techniques would be an advantage The appointment will be on the 1A scale £10,458 to £13,527 Applications should be sent by 1st December to Dr J A Lucas, Department of Botany, University Park, Nottingham NG7 2RD, from whom further details can be obtained (2087)A

nature

The international journal of science with 500,000 readers throughout the world seeks

A TALENTED BIOLOGIST

Essential qualifications

- A sound education in some field of biology
- A critical and lively interest in science in general
- A sense of literacy

Research experience desirable

Applications are invited from people seeking a career in the communication of science The successful applicant will join the team responsible for assessing and editing biology manuscripts, either in Washington or in London

There will be opportunities for contributing to *Nature* in other ways Research experience in neurobiology or immunology would be particularly welcome, but those with other interests should not be deterred from applying

US applicants should send their *curriculum vitae*, with a detailed account of their education, research experience and literary skills, to the

Editor, *Nature*,
1137 National Press Building,
Washington, DC 20045

by 20 November and be prepared to be interviewed in Washington shortly thereafter

Applications from elsewhere should be sent to the

Editor, *Nature*,

UNIVERSITY OF CAMBRIDGE DEPARTMENT OF ZOOLOGY

UNIVERSITY LECTURESHIP

Applications are invited for a Lectureship in the Department of Zoology Applicants should have a research interest in the field of Cell Biology, preferably in the cytoskeleton or a related area The Department has a strong interest in many aspects of biological science, including cell and molecular biology, developmental biology and neurobiology

The appointment to the lectureship will be for 3 years in the first instance, with the possibility of reappointment to the retiring age The scale of stipends for a University Lecturer not ordinarily resident in College is £14,169 pa, rising by eleven annual increments to £21,850

Please ask for further information on the post and the Department from **John Andrews, Secretary to the Appointments Committee for the Faculty of Biology 'A', Department of Zoology, Downing Street, Cambridge, CB2 3EJ Tel 0223 336621 (International + 44 223 336676)** Applications (twelve copies) should include a *curriculum vitae*, list of publications, statement of intended research and the names of not more than three referees The closing date has been extended to Friday 22 December 1989 (2081)A

The University of Manitoba
Faculty of Science

VIROLOGIST/MOLECULAR BIOLOGIST

The Department of Medical Microbiology, University of Manitoba, invites applications for a tenure-track position at the rank of Assistant or Associate Professor, beginning July 1, 1990

Applicants should hold a Ph D or M D degree or both, and should have research experience and a strong publication record in Virology/Molecular Biology of microbial pathogens Other areas of research in cell biology/microbiology will also be considered The successful candidate will be expected to establish an active research program and participate in undergraduate medical and graduate teaching programs Salary will be commensurate with experience and qualifications

Both women and men are encouraged to apply In accordance with Canada Immigration, priority will be given to Canadian citizens or permanent residents

Send curriculum vitae, a summary of research interests, and names and addresses of three referees to **Dr Robert Brunham, Professor and Chairman, Department of Medical Microbiology, University of Manitoba, 543-730 William Avenue, Winnipeg, Manitoba, Canada, R3E 0W3** Applications will be received until January 31, 1990 (NW4581)A

DREXEL UNIVERSITY ENDOWED CHAIR ECOLOGY, ENVIRONMENTAL SCIENCE

Nominations and applications are sought for an outstanding scientist to occupy an endowed chair in the College of Science named in honor of L Drew Betz, Drexel alumnus and founder of Betz Laboratories, Inc We seek an individual who will provide a focus of excellence for research, instruction, and interaction with students in areas related to ecology and the environment The Bioscience Department has interests in ecology, environmental science, biochemistry and molecular biology and the University's Institute for Environmental Studies has interests in water and air quality, water supply, and solid waste management Initial screening for the position will begin 15 December 1989 and continue until a suitable candidate is found, or until Aug 31, 1990

Submit nominations, inquiries, curriculum vitae, statement of interests, and names of at least three references to **Dr James R Spotila, Chairman Betz Chair Search Committee Department of Bioscience and Biotechnology Drexel University, Philadelphia, PA 19104**

Drexel University is an Equal Opportunity/Affirmative Action Institution and invites applications from women and minorities (NW4572)A

POSTDOCTORAL TRAINING IN CELL REGULATION

The Department of Biochemistry, St Jude Children's Research Hospital, announces a training program in the molecular and cellular biology of cell growth, differenti-ation and transformation The program emphasizes a multidisciplinary approach that develops skills in biochemistry, molecular genetics and cell biology Fellows benefit from training in energetic, well-funded laboratories within an expanding research institute We offer competitive stipends plus the benefit of living in a grow-ng, economical, sunbelt community Specific research groups participating in the program include

W Y Cheung	Regulatory properties and biological functions of calmodulin, Ca^{2+} regulated enzymes
Cleveland	Growth factor signal transduction and regulation of gene transcription
A Fried	The ubiquitin system and post-translational regulatory pathways
N Ihle	Mechanisms of hematopoietic stem cell growth regulation, differentiation and transformation
S Jackowski	Regulation of phospholipid metabolism and the production of lipid-derived second messengers
C Rock	Cell cycle regulation of membrane biogenesis
E Thomas	Antimicrobial and antitumor mechanisms of leukocytes

Further information on individual research programs can be obtained by writing the Department of Biochemistry Applicants should indicate the research group(s) they are nterested in, submit a brief statement of their research nterests, curriculum vitae, reprints, and names of three references to

UNIVERSITY COLLEGE LONDON
UNIVERSITY OF LONDON
INSTITUTE OF ARCHAEOLOGY
READER/SENIOR LECTURER IN ARCHAEOLOGICAL CONSERVATION AND/OR MATERIALS SCIENCE

Applications or nominations are invited for this senior position in the nstitute of Archaeology The appointee will be expected to provide research leadership in the conservation of archaeological and ethnographic materials and/or in the science of materials used in antiquity and by pre-industrial societies He/she will contribute actively to the further development of conservation within the internationally known Department of Archeological Conservation and Materials Science, and will share in the undergraduate and postgraduate teaching in the Department which provides courses in conservation, ancient materials technology, and museum studies He/she will be expected to take a major role in the planning and implementation of the Institute's projected new Centre for Conservation and Museum Sciences, and to participate in fund-raising activities

The successful applicant will have research experience in an appropriate scientific discipline such as applied chemistry or materials science, preferably with expertise in conservation or in the study of ancient materials Applicants may be from university, museum, governmental or commercial organisations The initial salary will be in the range £23,139 – £27,903 pa inclusive of London weighting

Applications or nominations (one copy suitable for photographic reproduction) giving full details of qualifications and experience, and the names of three referees, should be sent **not later than 31 January 1990 to the Director's Personal Assistant, Institute of Archaeology, University College London, 31-34 Gordon Square, London WC1H 0PY** (FAX Number 01 387 8057) from whom further particulars can be obtained

Equal opportunities employer (2086)A

UNIVERSITY OF NATAL

PIETERMARITZBURG,
SOUTH AFRICA

The University of Natal rejects apartheid It is an equal opportunity, affirmative action University

Faculty of Agriculture

Professor of Crop Science

The South African Sugar Association Chair of Crop Science

Ref P93/89
Closing date 10 January 1990

The Department of Agronomy (which includes the sub-disciplines of Crop Science Soil Science and Agrometeorology), specifically the Crop Science Section provide broad-based curricula designed to equip graduates for careers in research extension and crop production in both commercial and subsistence agriculture sectors and has an active postgraduate school Majors in agrometeorology and soil science are also offered in the combined Department

Applicants should hold a doctoral degree

Chair of Genetics

Ref P91/89
Closing date 10 January 1990

The Department of Genetics is housed in the Faculty of Agriculture and is responsible for teaching and research in Molecular Genetics, Quantitative Genetics and Plant Breeding Students are attracted from both the Faculties of Agriculture and Science

Scientists with teaching and research experience in at least one of the above fields of genetics are invited to apply for the vacant professorship

A doctorate in genetics is essential and applicants must be able to provide academic leadership and should have a proven record of achievement in teaching post-graduate supervision and research

The salaries offered will be determined according to the qualifications and/or experience of the successful applicants

Application forms, details of the salary package, further particulars of the posts and conditions of service are obtainable from the Personnel Section, University of Natal, P O Box 375, Pietermaritzburg 3200, South Africa, telephone (0331) 63320, fax no 27-0331-63497 or the Secretary, South African Universities Office, Second Floor, 16 Charles II Street, London SWIY 4QU, telephone 01-839-3420 or 01-839-4388, fax no 01-839-3480

CHAIR

ENVIRONMENTAL TOXICOLOGY GRADUATE PROGRAM

UNIVERSITY OF CALIFORNIA, RIVERSIDE

Nominations and applications are invited for the Chair of the Environmental Toxicology Graduate Program at the University of California, Riverside Candidates are expected to have an internationally recognized research program utilizing biochemical, cellular and/or molecular approaches towards understanding fundamental mechanisms of toxic action in biological systems In addition, the Chair must have demonstrated teaching excellence, administrative ability, leadership and enthusiasm to administer an interdepartmental program while continuing an active research program

The Interdepartmental Environmental Toxicology Graduate Program is administered from the Department of Entomology and includes participating faculty from the Departments of Biochemistry, Botany and Plant Sciences, Chemistry, Nematology, Plant Pathology, Soil and Environmental Sciences, the Division of Biomedical Sciences and the Statewide Air Pollution Research Center The current research strength of faculty in this Program is on the biochemical, cellular and molecular mechanisms of toxicity of agricultural chemicals and other environmental toxicants, and on the fate and transformation of these toxicants in the environment

The appointment of the Chair, whose major research and teaching responsibility is to the Environmental Toxicology Graduate Program, will be at the tenured Full Professor level in the Department of Entomology Teaching responsibilities will include graduate-level instruction and supervision of graduate students in the Environmental Toxicology Program The appointees will also have the opportunity to be involved in other Interdepartmental Graduate Programs on campus

Submit a detailed curriculum vitae, list of publications, representative reprints, a statement of research interests, and names and addresses of six referees to

S S Gill, Search Committee Chairman, Department of Entomology and the Environmental Toxicology Graduate Program, University of California, Riverside, CA 92521 Applications and nominations accepted until February 1, 1990

The University of California is an Equal Opportunity/Affirmative Action Employer, and Minorities and Women are particularly encouraged to apply (NW4590)A

CLINICAL PHARMACOLOGIST - PHYSIOLOGICAL PHARMACOKINETICIST

The Laboratory of Clinical Studies, National Institute on Alcohol Abuse and Alcoholism, Public Health Service, invites applications for one Clinical Pharmacologist - Physiological Pharmacokineticist This position is offered depending on the experience of the applicants at the level of a senior staff fellow (salary range, $28,000 - $45,234) The Laboratory is involved in exciting studies on brain imaging and drug metabolism The individual appointed will have an important role in this multidisciplinary team effort A research ward, excellent analytical chemistry, brain imaging and computer resources are available in the Laboratory on the NIH campus Position information and qualification requirements may be obtained by contacting Dr Linnoila Submit Curriculum Vitae and names of three references to

Markku Linnoila, M D , Ph D
Clinical Director
National Institutes of Health
Building 10, Room 3B-19

The successful applicant will teach courses in sedimentology, applied palaeontology and stratigraphic analysis

Post B: SEDIMENTARY PETROLOGIST

Preference will be given to applicants with a PhD and an ability to teach sedimentology at all levels as well as supervising higher degree candidates

Salary scale Lecturer Z$22,488-Z$31,692, Senior Lecturer Z$32,736-Z$35,436, Associate Professor Z$36,492-Z$37,680

Appointment on the above scales will be according to qualification and experience

CONDITIONS OF SERVICE Both permanent and short-term contracts are offered Persons who are not Zimbabwean citizens may be appointed only on a short-term contract basis for an initial period of two years Short-term contract may be extended

Six copies of applications quoting ref ASA/17/10/89 and giving full personal particulars which should include full name, place and date of birth, qualifications, employment and experience, present salary, date of availability, telephone number and names and addresses of three referees should be addressed to **Deputy Registrar (Administration), University of Zimbabwe, P O Box MP 167, Mount Pleasant, Harare, Zimbabwe,** (Telegrams UNIVERSITY Telex 4-152 ZW)

Closing date for receipt of applications for the posts is *7 December 1989*

Applicants from outside Zimbabwe should also send a copy to the **Appointments Officer, Association of Commonwealth Universities, 36 Gordon Square, London WC1H 0PF, UK,** from whom further information may be obtained (W6719)A

ASSISTANT PROFESSOR OF INORGANIC CHEMISTRY

The Department of Chemistry University of Winnipeg, invites applications for a tenure-track appointment to begin July 1990 A Ph D in Inorganic Chemistry is required, preferably with post-doctoral research experience The University is primarily an undergraduate institution committed to excellence in teaching and research The responsibilities include teaching inorganic chemistry, the accompanying laboratory, and some introductory chemistry, as well as the development of a research program

Applications consisting of a curriculum vitae, outline of research interests, and names and addresses of three referees should be sent, by January 15, 1990, to **Dr H M Hutton, Chairman, Department of Chemistry, University of Winnipeg, Winnipeg, Manitoba, Canada, R3B 2E9** *In accordance with Canadian Immigration regulations, this advertisement is directed to Canadian citizens and permanent residents of Canada* (NW4580)A

THE WELLESLEY HOSPITAL RESEARCH INSTITUTE AND DEPARTMENT OF IMMUNOLOGY UNIVERSITY OF TORONTO

Applications are invited for the position of

LEADER

of a new basic research initiative to investigate cellular and molecular aspects of immunoregulation and autoimmunity

Applicants (Ph D or M D) for the program leader should be at the Associate or Full Professor level

The leader will be responsible for recruiting three additional individuals at the Assistant or Associate Professor (Ph D or M D) level Salary commensurate with experience The Institute will provide ample space and generous start-up funds in addition to substantial ongoing administrative funding Consideration in the first instance will be given to Canadian citizens Application deadline is January 1, 1990

Enquiries and curriculum vitae should be directed to **Dr E C Keystone, c/o Research Office, The Wellesley Hospital, University of Toronto, 160 Wellesley St East, Toronto, Canada M4Y 1J3** (NW4596)A

Pediatrician/immunogeneticist/molecular biologist

A position is available as Research Assistant Professor in the Department of Microbiology, Southwestern Medical Center The ideal candidate would have a background in pediatrics and have at least three years postdoctoral experience in immunogenetics/molecular biology Modest patient contact, 90% laboratory protected time to study the development of the human immune repertoire Experience with EBV transformation, polymerase chain reaction, cloning & sequencing of DNA, idiotype analysis, etc Send curriculum vitae and two letters of recommendation to **Dr J Donald Capra, Department of Microbiology, The University of Texas Southwestern Medical Center, 5323 Harry Hines Blvd , Dallas, Texas 75235** *The University of Texas Southwestern Medical Center is an equal opportunity employer* (NW4582)A

MEDICAL RESEARCH COUNCIL

RADIOBIOLOGY UNIT, OXON

Cell and Molecular Biology Division

MOLECULAR/CELLULAR BIOLOGISTS

Applications are invited for two non-clinical scientific posts One of these posts is a SHORT TERM appointment of 5 years, while the other may be filled by either a SHORT TERM appointment of 5 years or a CAREER appointment according to the age and experience of the successful candidate A career appointment will be tenable at this Unit in the first instance

The successful candidates will join a group studying molecular and cellular aspects of DNA repair and radiation mutagenesis, chromosome replication and aberration induction and the biophysics of radiation damage Excellent research facilities are available and the Unit also includes groups studying mammalian genetics, radiation leukaemogenesis, cancer therapy and radiation chemistry The postholders will be required to continue and expand the current programme on DNA repair and mutagenesis, in addition, a career appointment will develop his/her own programme of research and promote studies involving molecular biology

Salary on scales equivalent to those for University non-clinical academic staff, Grade 2/1 £12,381-£20,469, or for Senior Grade up to £24,285pa Pension provision The Unit is situated in a pleasant rural area a few miles from Oxford Hostel accommodation available

Please send applications, including full c v , publication list and the names and addresses of 2 referees, to the Personnel Officer, MRC Radiobiology Unit, Chilton, Didcot, Oxon, OX11 0RD Please telephone Dr John Thacker on (0235) 834393 for further information Closing date 15th December 1989

The Council is an Equal Opportunity Employer (2092)A

UNIVERSITY OF DURHAM

DEPARTMENT OF ARCHAEOLOGY

IMAGING ARCHAEOLOGICAL STRUCTURES BY ELECTRICAL RESISTIVIT TOMOGRAPHY

(Re-advertisement)

Applications are invited for a Po doctoral Research Assistant Imaging Archaeological Structu by Electrical Resistivity Tom raphy for a research project fund by SERC in conjunction w Geoscan Research

Geophysical surveys now pla crucial role in archaeological c servation, excavation plann and resource assessment Exist techniques generally provide o 2-D area maps over buried featu with minimal depth informati This project will transfer rec developments in medical imag technology to archaeology by veloping a novel electrical resist ity tomography system capable resolving archaeological structu in 3-D The research will invo theoretical studies, numer simulation, laboratory and fi experiments with interaction tween the archaeological, med and physical sciences Suitable c didates will have a strong ba ground in applied mathemat physics, geophysics or related fiel

The appointment is tenable three years from as soon as poss and the initial salary will be on Research Staff Scale Grade (£10,458-£12,381 p a) Inform enquiries may be made to Dr Noel, Department of Archaeolo (091) 374 3631

Further particulars (quot reference SS/AS/89 04) may obtained from the Registrar a Secretary (Faculty of So Sciences), University of Durha Old Shire Hall, Old Elvet, Durh DH1 3HP, telephone (091) 2995, to whom applications (th copies), including the names a addresses of three referees, sho be sent not later than Wednesda December 1989 Previous can dates need NOT apply (2074)A

FACULTY POSITIONS IN PHYSICAL OCEANOGRAPHY

The University of Miami invites applications for academic and research faculty positions (one each) in the Rosenstiel School of Marine and Atmospheric Science, Division of Meteorology and Physical Oceanography Rank and salary will be negotiated according to qualifications Minimum requirements are a Ph D Degree in physical oceanography or a closely related discipline, and demonstrated independent research capability Graduate level teaching competence in fluid mechanics with emphasis on large scale dvnamics or on boundary layer processes is desirable for the academic position

The appointees in these positions are expected to develop individual research activities which complement an active program of ocean dynamics research based on in situ field observations, satellite remote sensing, and researchers in NOAA's Atlantic Oceanographic and Meteorological Laboratories, which are located nearby A central interest in applications of space-based observing techniques to oceanic studies and dynamic analysis based on either, or a combination of, field experiments and model simulations, is particularly appropriate, as would be an interest in personal participation in field or numerical model studies

Send curriculum vitae, publication list and names of three references by 15 December 1989 for the research position and 15 January 1990 for the academic position to **Chairman, Physical Oceanography Search, Division of Meteorology and Physical Oceanography, Rosenstiel School of Marine and Atmospheric Science, University of Miami, 4600 Rickenbacker Causeway, Miami, FL 33149-1098**

The University of Miami is an Affirmative Action/Equal Opportunity Employer (NW4592)A

UNIVERSITY OF MICHIGAN

Invertebrate Paleontologist

The Museum of Paleontology and Department of Geological Sciences invite applications for a joint tenure-track position in invertebrate paleontology The position will be at the rank of ASSISTANT PROFESSOR, with appointment to be made in 1990 PhD is required We seek applicants with broad research and teaching interests in paleobiology, and expertise in the systematics of fossil invertebrates (metazoan and/or protistan) Current faculty in paleontology are C B Beck, D C Fisher, P D Gingerich, and G R Smith Resources include strong programs in organismal and evolutionary biology within the university Museum appointment involves shared curatorial responsibility for a major invertebrate research collection Interested candidates should send a resume, names of five persons from whom the Museum and Department may request letters of recommendation, and a brief statement of research interests, to **Prof Daniel C Fisher, Search Committee Chairman, Museum of Paleontology, The University of Michigan, Ann Arbor MI 48109-1079, U S A** Closing date for applications is January 31, 1990 The University of Michigan is a non-discriminatory, affirmative action employer (NW4594)A

STAFF TOXICOLOGIST

The California State Department of Health Services is recruiting for Staff Toxicologist for immediate openings An employment examination is scheduled for fall, 1989 The examination will be based 100 per cent on interviews Telephone interviews are permissible Vacancies exist in Sacramento, Emeryville, Berkeley, and Los Angeles The areas of involvement will be environmental toxicology and risk assessment The annual salary will start at $50,748-$61,392 To qualify for the Staff Toxicologist exam, you must have a Doctoral Degree in toxicology, biochemistry, pharmacology or a closely related specialty and three years of postdoctoral experience in toxicology Please send your resume to

State Department of Health Services
Office of Environmental

STUDENTSHIPS

DURHAM UNIVERSITY/SHELL RESEARCH LTD

RESEARCH STUDENTSHIPS/ VIBRATIONAL SPECTROSCOPY

Investigations of interactions of polymer surfactants at solid/liquid Interfaces

This project is related to understanding how polymer surfactants cause stabilised dispersions of soot (and other particles) in automative fuels and lubricants The degree and nature of adsorption of relevant model detergents on a variety of substrates (carbon, silica etc) will be studied using infrared reflection and photoacoustic spectroscopy These measurements, backed up with oscillation rheology and photon correlation spectroscopy, will be employed to relate chemical (molecular) structure with adsorption efficiency In this way it is hoped to build up a better picture of factors influencing the stabilisation of suspensions The project will also include some work on the adsorption of lubricant (surfactant) additives on metal surfaces — in connection with the control of anti-wear properties

Applicants from EEC countries should have a first degree (or equivalent diploma) in Chemistry, Physics or Chemical Physics The studentship attracts a grant of £3,725 p a , (tax free) plus an additional £550 per annum subject to report There will be an opportunity to work at a modern industrial research laboratory (Shell Research Laboratories, Thornton Research Centre, Nr Chester) Applications to Dr J Yarwood (Tel 091-374-3136 or FAX 091-374-3741 Chemistry Department, Durham University, South Road, Durham DH1 3LE, U K as soon as possible (2094)F

continued on page 16

University of Tromsø

HEART RESEARCH

The University of Tromsø has an immediate opening for
A PROFESSOR OF PHYSIOLOGY
until January 1, 1993, with possibility of extension The position is attached to the Department of Medical Physiology which concentrates its activity on experimental heart research This includes studies of cardiac electrophysiology and pharmacology, heart failure, arrhythmias and antiarrhythmic drugs, hemodynamics, ischemia and reperfusion, and hypothermia The Department is equipped for in vitro studies of isolated heart cells and heart tissues, as well as in vivo studies of anesthetized dogs and other animals Applicants are expected to strengthen this research, and must therefore possess research experience and supervising ability in experimental heart research Lectures may be held in English, but as the position also entails administrative work, the successful applicant is expected to learn Norwegian

The Department of Medical Physiology has 2 professors, 2 assistant professors plus research fellows (approx 10) and technical support staff (approx 6)

The gross salary is at present NOK 276 792 per year Applications including a complete c v and list of publications should be sent in 5 copies together with the relevant certificates to
The University of Tromsø, The University Director, Breivika, N-9000 TROMSØ, NORWAY.
Closing date for applications 29 December 1989
Full directives for application and further information about the professorship can be obtained at the University at the abovementioned address, or from Professor Helge Refsum, Institute of Medical Biology, University of Tromsø, Teoribygget, N-9000 Tromsø, NORWAY Tel 47 83-44693 , (W6732)A FRANTZ HRA 89

STUDENTSHIPS continued

UNIVERSITY OF ST ANDREWS
DEPARTMENT OF BIOLOGY & PRECLINICAL MEDICINE
NERC STUDENTSHIP

Applications are invited for a three year studentship, leading to a Ph D , to investigate antibacterial immunity in marine invertebrates The project will be concerned with the interaction between marine micro organisms and marine decapod crustaceans and will be based at the Gatty Marine Laboratory, St Andrews The studentship, supervised by Dr V J Smith, is available immediately

Applicants should have an interest in marine microbiology or the physiology of marine animals and should possess a First or Upper Second Class Honours degree in Biology, Microbiology or another appropriate subject Further information can be obtained from **Dr V J Smith, Gatty Marine Laboratory, University of St Andrews, Fife, KY16 8LB, (tel (0334) 76161 ext 7270)**, to whom applications should be sent by 5th December 1989 (2097)F

THE ROYAL SOCIETY
JOHN MURRAY TRAVELLING STUDENTSHIP IN OCEANOGRAPHY AND LIMNOLOGY 1990

Applications are invited for the above Studentship, open to British graduates under the age of 35, for the encouragement of travel and work in oceanography or limnology This award, which may be held for periods from three months to one year, will in 1990 be up to £2500, adjusted according to qualifications and place and duration of research Applications are especially invited from workers in oceanography and limnology, as well as in zoology, botany, geology, mathematics and physics, and it will be permitted to hold the award while receiving a salary from a regular appointment

Applications receivable by 15 December 1989 should be made on forms obtainable from **Mrs U M A Tokle, The Royal Society, 6 Carlton House Terrace, London, SW1Y 5AG** (1927)F

FELLOWSHIPS continued

FEBS LONG-TERM FELLOWSHIPS

These Fellowships are intended to support one year stays of members of FEBS constituent Societies in a laboratory of another country within the FEBS area There is a possibility of renewal for a further one year period The amount of money allocated per Fellowship will be up to 32000 DM plus travel expenses to and from the receiving laboratory and town of origin A family help up to 3600 DM may be provided

Eligible candidates must have been members of a FEBS constituent Society for at least one year before the application is submitted They should be normally less than 35 years old at the time of application Applications to work in a laboratory in the same country in which the applicant is working or normally works are not considered

Applications shall be received by the Chairman of the Fellowships Committee before April 1st Fellowships will be awarded during the next FEBS Meeting (Budapest, August 1990) Retrospective applications cannot be considered

Application forms and additional information may be obtained from the Chairman of the Fellowships Committee Dr C Gancedo, Instituto Investigaciones Biomédicas CSIC, C/Arturo Duperier 4 E-28029 Madrid, Spain (W6712)E

GULBENKIAN INSTITUTE OF SCIENCE
Oeiras, Portugal
GULBENKIAN RESEARCH FELLOWSHIPS IN BIOLOGY

The Department of Science of the Calouste Gulbenkian Foundation is offering two research fellowships for postdoctoral scientists wanting to work at the Gulbenkian Institute of Science (Biology), Oeiras, Portugal Candidates should be able to work in one of the following areas

- ★ *Neurobiology of purines*
- ★ *Membrane transport in yeasts*
- ★ *Molecular yeast taxonomy*
- ★ *Molecular Biology of stress in yeasts*
- ★ *Structure and function of P450 genes and nRNA in the liver*
- ★ *Mathematical methods in neurodynamics and neuromuscular control*

The fellowships are for two years The stipend is 200 000 portuguese escudos per month Travel assistance may be provided

Applications should be submitted in duplicate to the **Director, Gulbenkian Institute of Science, Apartado 14, 2781 Oeiras Codex, Portugal** They should include a curriculum vitae, the area of research selected from one of those indicated above, and the names and addresses of two referees The closing date is 31 of December (W6720)E

GONVILLE AND CAIUS COLLEGE, CAMBRIDGE
MEDICAL RESEARCH FELLOWSHIP

Gonville and Caius College intends to elect a Research Fellow in some field of medical research Candidates should be medical graduates who are registered with the General Medical Council and will normally be below the age of 35 Candidates will be expected to have undertaken sufficient previous research to be able to demonstrate their research ability The Fellowship will be tenable for up to four years and is particularly directed towards those intending to pursue a career in medical research

The stipend of the Research Fellow will be related to the University's clinical lecturer scale (currently £14,545 – £25,500) if the Fellow is engaged in research involving clinical responsibility and otherwise to the University's senior clinical research associate scale (currently £15,105 – £19,310) Initial placement will depend on age and experience There will be a deduction if the Fellow is resident in College Where appropriate, the College intends to negotiate a suitable honorary clinical contract with the Health Authority

The Research Fellow will receive the normal privileges of a Fellow of the College, including High Table meals and other allowances The College can assist its Research Fellows by contributing towards research expenses

Further details can be obtained from the **Master's Secretary, Gonville and Caius College, Cambridge CB2 1TA** Applications must be received by 15 January (2091)E

The Royal Society

UNIVERSITY RESEARCH FELLOWSHIPS

The Council of the Royal Society invites applications for about 28 appointments to be supported from the Society's Parliamentary Grant-in-aid and tenable from 1 October 1990 as Royal Society University Research Fellowships

All applicants must have a Ph D or equivalent research experience, they must be at least 26 but should not have passed their 33rd birthdays by 1 October 1990 In an exceptional case, however, an award may be made to an applicant who has passed his/her 33rd birthday by this date but who has outstanding ability for ndependent scientific research and who is able to demonstrate that there are special reasons why he/she should still be eligible for a fixed-term research fellowship Applicants must be British Citizens of the United Kingdom) and must hold the appointments in departments of science (including agriculture, medicine, mathematics, engineering and technology) in universities or polytechnics in the United Kingdom Persons already holding substantive posts in universities or polytechnics in the United Kingdom will not normally be considered

Appointments, which will be subject to the Society's General Regulations governing Royal Society Research Appointments, will be for up to five years with the possibility of renewal for two successive periods of up to three and two years respectively Salary, irrespective of where the appointment is held, will be on the University Lecturers' scale for non-clinical academic and related staff with entry point related to age and London Allowance where appropriate Research expenses up to £5000 will be available, with the ability to bid for higher figures

The primary criterion for selection will be the scientific merit of the ndividual applicant based on his or her record so far and on future potential Account will be taken of the facilities and intellectual environment being offered by the prospective host department

Applicants who were unsuccessful in previous years should not be deterred from applying in 1990 if they are eligible to do so They should, however, make a fresh application on a new application form and arrange for updated statements from referees to be provided

ROYAL SOCIETY LEVERHULME TRUST SENIOR RESEARCH FELLOWSHIPS

The Council of the Royal Society invites applications from scientists n any subject, including mathematics and engineering, for five appointments from 1 October 1990 to Royal Society Leverhulme Trust Senior Research Fellowships The fellowships have been established through the generosity of Leverhulme Trust to provide opportunities for scientists in mid-career to be relieved of all eaching and administrative duties for a period between one academic term and one year, to do full-time research

Applicants must be aged between 35 and 55, hold a Ph D or have equivalent research experience, and hold a substantive post in a British university or polytechnic Employees of Research Councils, or those in Governmental or other research institutions, will not be eligible The fellowship will normally, but need not necessarily, be held at the applicant's own institution, but may be held at any higher educational or research institution, or industrial research organization, in the UK approved by the Council of tne Royal Society

Fellows will continue to be paid by their employers, the fellow's employing institution will be reimbursed for the full salary costs, ncluding USS and ERNI but not including institutional overheads or other costs The applicant's employing institution will be required to show that appropriate arrangements have been made to cover the applicant's teaching and administrative duties, although the fellow may continue with the supervision of postgraduate or postdoctoral esearch students Fellows may apply for research expenses to cover the costs of consumables, etc , grants cannot be made for equipment The Society will consider further requests for additional grants for travel to conferences or overseas laboratories

RESEARCH FELLOWSHIPS

The Council of the Royal Society invites applications for three appointments, two **EPA Cephalosporin Fund Research Fellowships** and one **Pickering Research Fellowship**, in the areas of medical, biological or chemical sciences, at least one of which, the Pickering Research Fellowship, will be made in the area of botany or chemistry

The Head Bequest Committee of the Royal Society invites applications for the **Henry Head Research Fellowship** for original research in neurology in its widest aspects

Conditions of tenure

All the appointments are subject to the Society's General Regulations Governing Royal Society Research Appointments All candidates must have a Ph D or equivalent research experience and there are no restrictions on nationality or place of tenure

Tenure for all appointments is three years in the first instance from 1 October 1990 and renewable for a further two years Superannuation benefits will be provided and research expenses up to £5000 will be available, with the ability to bid for higher figures The point of entry on the salary scale will be determined by Council or the Head Bequest Committee

Salary

Salary scale (for all appointments) £16 207 x £669 to £18 883 x £657 to £20 854 x £705 to £23 674 per annum

Age limit Over 33 and preferably below 40 on 1 October 1990

ROYAL SOCIETY–BOC LIMITED RESEARCH FELLOWSHIP

Applications are invited by the Council of the Royal Society for the Royal Society–BOC Limited Research Fellowship for independent and original scientific, technological or engineering research in a field of direct interest to BOC Limited BOC Limited is a wholly-owned subsidiary of the BOC Limited Group plc, which is an international company manufacturing and marketing a range of products including gases and related products, it has additional interests in health care, high vacuum technology, carbon and carbide products and distribution services The successful candidate will be expected to work on gases and related products which are the specific responsibility of BOC Limited, and will be expected to liaise closely with BOC Limited It is expected that applicants will establish a dialogue with the appropriate BOC Limited department before submitting their applications

Candidates must be citizens of a member country of the European Community and must hold the fellowship in a university or polytechnic department in the United Kingdom Applicants should preferably be under 33 on 1 October 1990

The appointment will be tenable for three years from 1 October 1990 and may exceptionally be renewable for a further two years, such renewal being considered at the end of the second year of tenure The stipend scale will be £15 538 x £669 to £18 883 per annum, and the point of entry will be determined by Council Superannuation benefits will be provided and, where appropriate, London Allowance Some provision for research expenses will be available

RUTHERFORD SCHOLARSHIP

This award, for graduates of exceptional promise and ability who are under 26 years of age on 1 May 1990, is for research in any branch of the natural sciences, with a preference for experimental physics if there are candidates of similar merit Two appointments will be tenable for three years, from 1 October 1990 or such other date as may be arranged, in some part of the British Commonwealth other than that in which the applicant graduated The value, adjusted to meet the circumstances, will be £5650 per annum on appointment if held in the United Kingdom, with allowances for travel, contribution to university fees, etc It will not normally be awarded to a graduate who has already held a senior research award

or all appointments apply (by letter) for application form and further details (*stating for which appointment*)

Address Mrs U M A Tokle, The Royal Society, 6 Carlton House Terrace, London SW1Y 5AG

Closing date 16 February 1990

No applications forms will be issued after 2 February 1990 and no applications arriving after 4 p m on 16 February will be considered

Graduate and Postdoctoral Fellowships

An interdisciplinary research program at Yale University sponsored by The McKnight Foundation

Applications are invited for Graduate and Postdoctoral Fellowships to join an interdisciplinary research program undertaken by ten faculty members in three departments at Yale University (Biology, Molecular Biophysics & Biochemistry, and Forestry & Environmental Studies)

Ongoing projects include the following

- genetic analysis of cell-cell interactions in floral structures
- mutational and molecular fine-structure analysis of floral genes
- ectopic expression of growth regulators in the flowering process

The training program also includes technical workshops, seminar programs, and extensive collaborative work. Graduate applicants must apply to the Director of Graduate Studies, Department of Biology, P O Box 6666, Yale University, New Haven, CT 06511 U S A, Telephone (203) 432-3538 by January 3, 1990 Postdoctoral applicants should apply directly to the Project Coordinator with CV, three letters of reference, and a research interest statement Postdoctoral fellows will be encouraged to develop independent collaborative projects on flowering

For further information, contact Prof. Ian Sussex (Project Coordinator), Yale Biology Department, P.O. Box 6666, New Haven, CT 06511 U.S.A.

Yale University is an Affirmative Action/Equal Opportunity Employer

(NW4576)E

HELLENIC PASTEUR INSTITUTE

POSTDOCTORAL FELLOWSHIP IN BIOCHEMISTRY

A postdoctoral position (2-3 years) is available for a young Biochemist or Biologist, to join a team studying membrane proteins, using biochemical approaches

Applications, including a C V and names of referees should be sent to Dr K Soteriadou, Department of Biochemistry, Hellenic Pasteur Institute, 127, Vas Sofias Ave, Athens 11521, Greece Fax 1-6423498 Tel 1-6430044 (W6715)E

The Queen's University of Belfast

RESEARCH FELLOWSHIP

Division of Biochemistry

Applications are invited from suitably qualified EC citizens, postdoctoral or postgraduate, for a fellowship to work with Dr R J H Davies on the photomodification of DNA, emphasising laser-induced processes and sequence-directed photosensitisation The research is part of a collaborative programme, funded by the EC, with groups at Trinity College, Dublin (Professor J M Kelly and D J McConnell) and the Museum National d'Histoire Naturelle, Paris (Professor C Helene and Dr T LeDoan) Generous travel funds are available for consultation and secondments between the participating laboratories The fellowship is available from 1 February 1990, or an agreed date thereafter for one year, with renewal by mutual agreement

Salary range £10,458–£14,169 per annum, placing depending on age, qualifications and experience with superannuation under USS

Informal enquiries may be made from Dr Davies, tel Belfast (0232) 329241 ext 2701

Applicants, quoting ref 89/R2, should submit a curriculum vitae, including the names and addresses of two referees, to the **Personnel Officer, The Queen's University of Belfast, Northern Ireland, BT7 1NN** Closing date 8 December 1989 *The University is an Equal Opportunity Employer* (2080)E

UNIVERSITY OF CANTERBURY

New Zealand

POSTDOCTORAL FELLOWSHIPS (CHEMISTRY, GEOGRAPHY, ZOOLOGY)

Applications are invited for three two-year University Grants Committee Post-Doctoral Fellowships

Chemistry

Test methods for aluminium toxicity in soils The Research Fellow will be expected to participate in an ongoing project on the development of field tests for the toxic fraction of aluminium soils (Ref C89/01) Enquiries may be made direct to Dr H K J Powell, Department of Chemistry

Geography

Climatic change, sea-level rise and hazards to coastal land, as these matters relate to ongoing research in the Department of Geography (Ref C89/02) Enquiries may be made direct to Dr R M Kirk, Department of Geography

Zoology

Salmon stock development The Fellow is expected to be competent in recombinant DNA technology (Ref C89/04) Enquiries may be made direct to Dr F Y T Sin, Department of Zoology

Applicants must be aged 35 years or less and have been awarded, or have qualified for the award of, the degree of Doctor of Philosophy, or a degree equivalent thereto, or have submitted a thesis for examination The age limit may be relaxed in special circumstances or in order to avoid hardship to an applicant for a Fellowship

The emolument for a Fellowship shall be at a rate not exceeding the lowest step of the Lecturer salary scale (NZ$36,000 per annum)

Before submitting a formal written application, candidates are requested to obtain further particulars and Conditions of Appointment from the Appointments Officer, Association of Commonwealth Universities, 36 Gordon Square, London WC1H 0PF

Applications quoting the appropriate reference code close with **A W Hayward, Registrar, University of Canterbury, Private Bag, Christchurch, New Zealand,** on 14 December 1989 (W6723)E

WELLCOME FELLOWSHIPS IN MEDICAL SCIENCE

Wellcome Trust Senior Research Fellowships in Medical Science in Australia

APPLICATIONS FOR 1991

The Trustees invite applications for two five year senior research fellowships to be held in biomedical science in Australia These fellowships, to commence in 1991, continue the scheme which has provided funding for twelve outstanding Australian biomedical researchers since 1984

Australian nationals who are either medically qualified or science graduates, probably aged between 30 and 37, who wish to make their career in Australia and undertake research in an Australian academic institution are eligible to apply whether or not they are currently working in Australia Direct personal enquiries by possible candidates are welcome but formal applications must be submitted by the Head of Department in the University where the candidate will work

The salary offered will be according to age and experience and on appropriate Australian academic scales with up to A$20,000 per annum ancillary support

Nominations must be submitted on the appropriate application form Closing date for the award is 31 January 1990 For information and application forms please contact

Dr Peter Castaldi
The Royal Australian College of Physicians
145 Macquarie Street
SYDNEY NSW 2000 AUSTRALIA

KING'S COLLEGE LONDON

(University of London)

GRADUATE RESEARCH ASSISTANTSHIP IN SYNTHETIC ORGANIC CHEMISTRY

A research assistant is required to work in collaboration with Professor C B Reese on the synthesis of compounds with potential anti-HIV and other antiviral activity

Applicants should hold First or Second Class Honours Degrees from UK universities (or CNAA) or GRSC of equivalent standing, and should have had practical experience of synthetic organic chemistry The post is available now and is tenable for up to three years Salary range £11,466–£18,315 pa including London Allowance with starting point according to age and experience, superannuation benefits are payable Applications together with a curriculum vitae and the names of two referees should be sent as soon as possible to Professor C B Reese FRS, Department of Chemistry, King's College London, Strand, London, WC2R 2LS (2078)P

AWARDS

THE CIBA-GEIGY PRIZE FOR RESEARCH IN ANIMAL HEALTH

The Animal Health Subdivision
of CIBA-GEIGY Limited,
Basel, Switzerland,
is pleased to announce that its Prize
for 1989 will be awarded to

Tilahun D Yilma, DVM PhD
of the
Department of Veterinary Microbiology
and Immunology,
School of Veterinary Medicine,
University of California,
Davis, USA

for his work on the
Development of an Infectious Vaccinia Virus
Recombinant Vaccine for Rinderpest.

The Prizegiving will take place in Basel
on February 7, 1990

(W6717)N 33283

GRANTS & SCHOLARSHIPS

BRITISH LUNG FOUNDATION RESEARCH GRANTS

Applicants are invited to apply for the following categories of awards

1 **Fellowships**
Funds are available to cover the cost of the salary of an individual research worker at the appropriate level for a stated period with an allowance for necessary supporting costs

2 **Project Grant**
Funds are available up to a value of £45,000 to cover any costs appropriate to a stated project This may include salary costs Applications will be considered for awards well below the maximum

3 **Equipment Grants**
Grants will be awarded to the cost of equipment up to a maximum value of £20,000

Awards are available for clinical and non-clinical applicants

Closing dates for applications 20th January 1990

Application forms are available from

BRITISH LUNG FOUNDATION
Kingsmead House, 250 Kings Road, London SW3 5UE

AWARDS

Australian Institute of Marine Science

POSTDOCTORAL AWARDS

The Australian Institute of Marine Science, an Australian Government Statutory Authority, is Australia's premier marine science research institute Its functions are to carry out research in marine science, to assist other persons and institutions engaged in research in this field and to disseminate information relating to marine science

The Institute buildings are located at Cape Ferguson, a coastal site 50 km from Townsville, and adjacent to the central section of the Great Barrier Reef

Up to three Postdoctoral Awards, each of 2 years, are granted each year by the AIMS Council, for research by scientists in the early stages of their postdoctoral career, who are of exceptional promise and have shown proven capacity for original work in marine science research

AIMS conducts its research within four (4) major research programs in an overall plan covering 1986-1991 These programs are Coastal Processes and Resources, Reef Studies, Environmental Studies and Biotechnology and Marine Systems Analysis and Oceanography A total staff of 130 including 29 PhD's is employed at AIMS in these programs The Institute provides excellent support including research funding, but specific requirements should be indentified by applicants for these awards A recently installed Bruker 300 MHz NMR Spectrometer is available for research applications

STIPEND Salary of A$31,525 per annum plus a district allowance of A$890 or A$460 per annum according to dependency

CONDITIONS Relocation costs including economy class airfare to Townsville for an awardee and dependant family and up to A$800 towards removal costs for personal effects are allowed Recreation and sick leave entitlements are the same as those applicable to AIMS employees

APPLICATIONS Persons wishing to apply for these awards should submit a complete **curriculum vitae,** a 2-3 page outline of a projected investigation and support requirements to the Secretary Australian Institute of Marine Science PMB No 3, Townsville MC, Queensland 4810, Australia You should also arrange for reports from three professional referees to be sent to the same address Applicants are encouraged to seek additional information on the Institute and its programs by telephoning the Director (077) 78 9211

Applications and referee reports should be received no later than 3 January 1990 for awards tenable normally not later than 1 May 1990

(W6726)N AR1 89 15 41057

GRANTS & SCHOLARSHIPS continued

ST JOHN'S COLLEGE, CAMBRIDGE

Research Studentships, 1990

The College invites applications for up to seven Research Studentships from men and women who are not already members of the College and who propose to register as Ph D students at the University The Studentships will normally be tenable for three years from October 1990 and of such value as will, in addition to the payment of fees, bring the student's total emoluments to £3,875 a year Applicants must have graduated in their first degree with first-class honours under the British system (or the equivalent grades or assessment overseas), or have a strong prospect of graduating at that level in examinations yet to be taken

Further details and application forms can be obtained from the **Tutor for Graduate Affairs (N), St John's College, Cambridge CB2 1TP** Completed applications must be received by 1 March 1990 (2072)H

THE ROYAL SOCIETY

MARINE SCIENCES RESEARCH GRANTS

1990

The Council of the Royal Society invotes applications from qualified research workers of Ph D or equivalent status for personal grants from three funds for marine sciences

- (a) *Browne Research Fund* for research in marine biology at a marine biological laboratory or elsewhere Preference will be given to those who propose to work on purely scientific problems rather than to those whose work would be primarily directed towards an economic end
- (b) *Maurice Hill Research Fund* established in memory of the late Dr M N Hill, F R S, for research in the general fields of physical and chemical oceanography, marine geophysics and geology, either at sea or in laboratories and institutes having adequate facilities
- (c) *Marshall and Orr Bequest* for the support of marine biological research

Grants may be used for periods up to one year, and are made on the understanding that university or other posts held by applicants will meanwhile be kept open for them Recipients are permitted to use grants while receiving salaries from regular appointments

In 1990 the total amounts available to be shared among all successful applicants will be about £8,000 from the Browne Research Fund, £19,000 from the Maurice Hill Research Fund and £24,800 from the Marshall and Orr Bequest, individual grants will not ordinarily be more than £2,500

Applications should be made on forms to be obtained from **Mrs U M A Tokle, The Royal Society, 6 Carlton House Terrace, London, SW1Y 5AG,** and returned by 15 December 1989 (1928)H

FELLOWSHIPS continued

DUBLIN CITY UNIVERSITY

DEPARTMENT OF CLINICAL MEDICINE

POSTDOCTORAL RESEARCH FELLOWSHIP

Applications are invited from candidates with Ph D's in Immunology or Biochemistry for a fellowship to study protein kinase C involvement in regulation of human T cell lymphoma proliferation and differation Experience with immunochemistry and/or molecular biology would be an advantage

Candidates should submit a full *curriculum vitae* together with the names of three referees to **Dr Dermot Kelleher, Department of Clinical Medicine, TCD Medical School Building, St James' Hospital, Dublin 8**

To arrive **not later than Friday, 8th December 1989** (2093)E

INSTITUT PASTEUR PARIS

Post-Doctoral Position

A fellowship is immediatel available to participate in research program supporte by the E E C concerning th establishment of the total nuc leotide sequence of the *Bacillu subtilis* chromosome Exper ience of molecular biolog would be an advantage

Please send CV, list of publi tions and names of reference to **Dr F KUNST, Instit Pasteur, Unité de Biochim Microbienne, 75724 Pa Cedex 15 (France) Phone 45-68-88-09** (W6730)

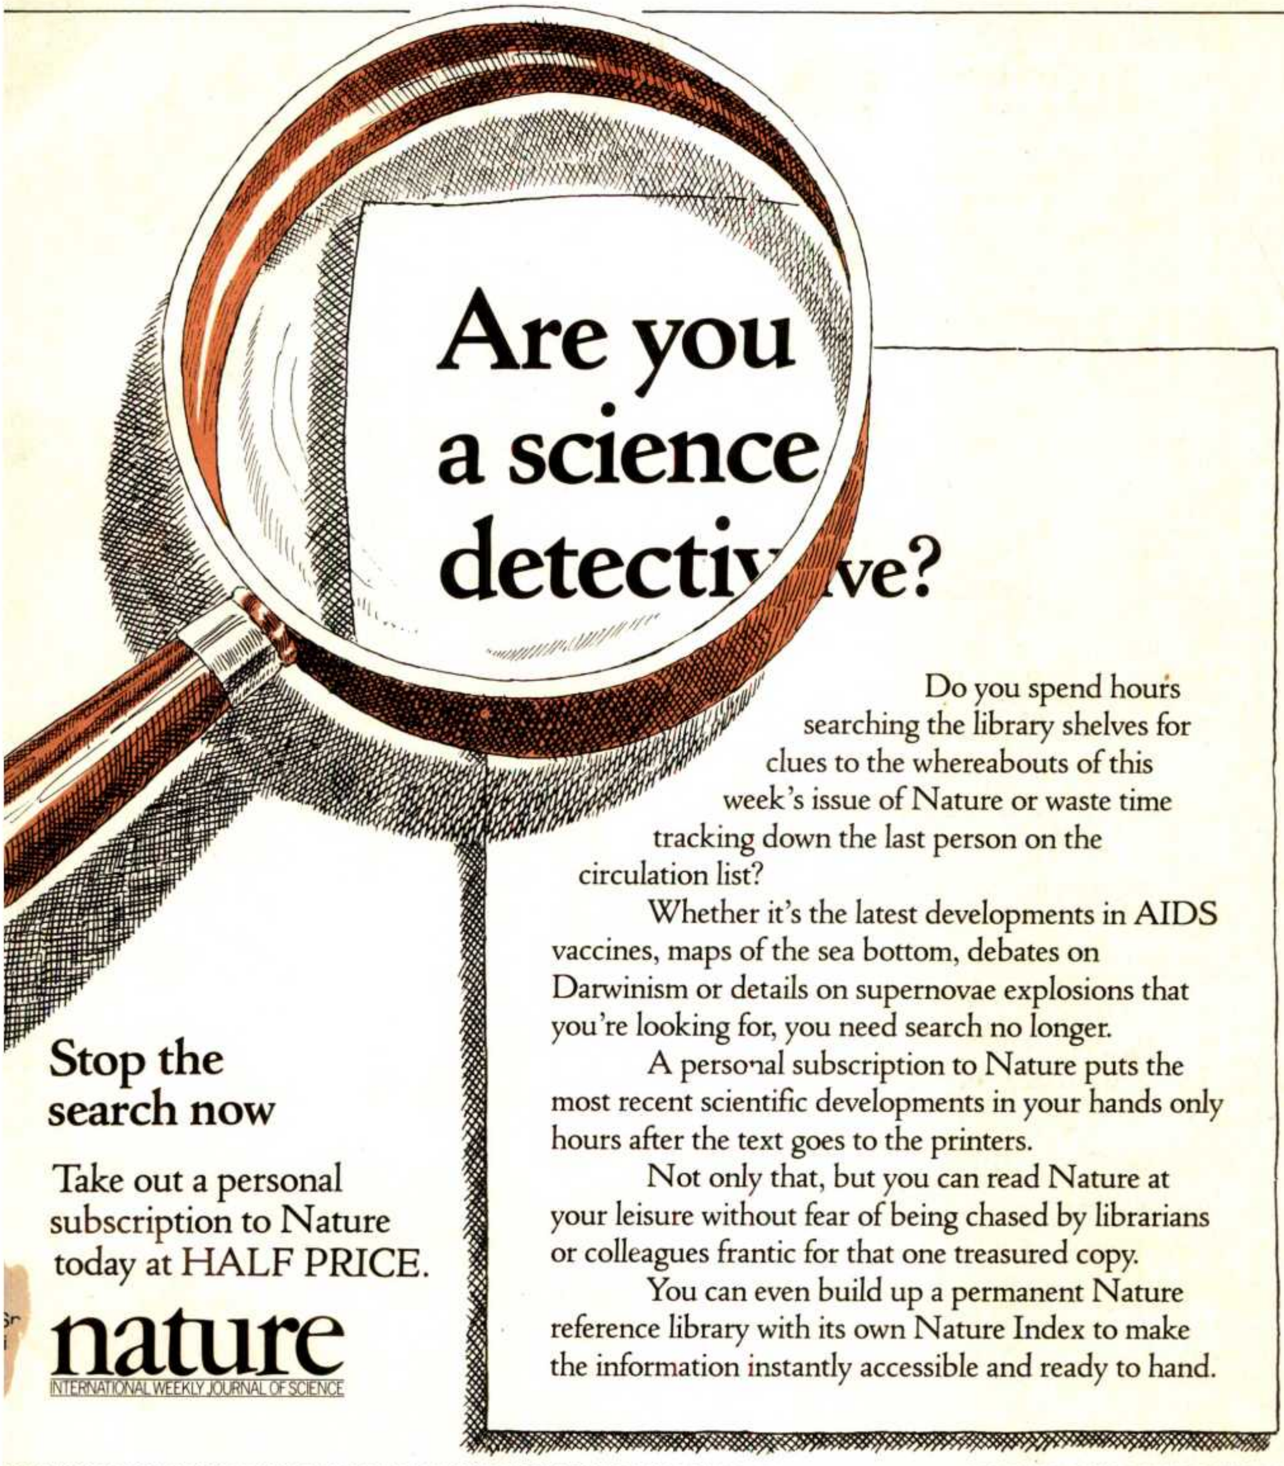
nature

— the world's most prestigious weekly journal of science



Are you a science detective?

Do you spend hours searching the library shelves for clues to the whereabouts of this week's issue of Nature or waste time tracking down the last person on the circulation list?

Whether it's the latest developments in AIDS vaccines, maps of the sea bottom, debates on Darwinism or details on supernovae explosions that you're looking for, you need search no longer.

A personal subscription to Nature puts the most recent scientific developments in your hands only hours after the text goes to the printers.

Not only that, but you can read Nature at your leisure without fear of being chased by librarians or colleagues frantic for that one treasured copy.

You can even build up a permanent Nature reference library with its own Nature Index to make the information instantly accessible and ready to hand.

Stop the search now

Take out a personal subscription to Nature today at HALF PRICE.

Introducing the ExoMeth™* Sequencing Kit from Stratagene

- New Method for Sequencing DNA Utilizing 5-methyl dCTP
- A Revolutionary Sequencing Paradigm - 10 Fold Faster
- No Minipreps
- No Restriction Mapping Necessary
- No Oligonucleotides
- No Mung Bean or S1 Nuclease
- No Transformations
- Ordered Strategy, No Shotgunning
- Utilizes Double Stranded Templates
- Utilizes T7 DNA Polymerase or Reverse Transcriptase

Contact Technical Services for Stratagene's ExoMeth™ Sequencing brochure.

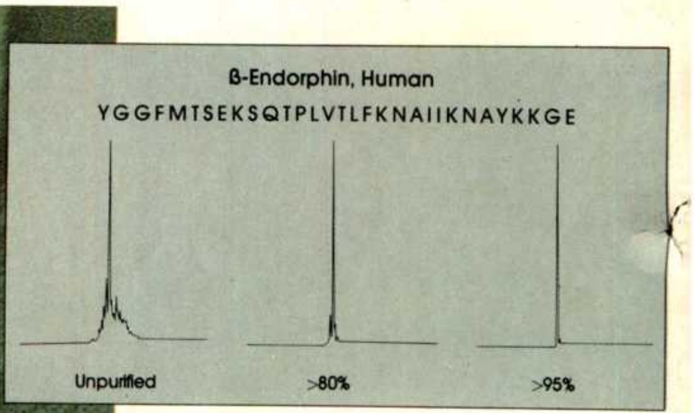
SCIENCE IN BRAZIL

NOW Purified Peptides

MPS specializes in quality, custom peptide synthesis . . . so you don't have to!

In order to meet the differing needs of individual researchers, we are now offering three grades of peptides: unpurified, >80% purity and >95% purity. Additionally, for those using peptides to raise anti-peptide antibodies, MPS also provides a peptide carrier conjugation service. Call us with your questions or if you would like a complete price list.



ß-Endorphin, Human

YGGFMTSEKSQTPLVTLFKNAIIKNAYKKGE

COMPARE OUR PRICES

MPS is offering custom peptides at the extraordinary prices listed below.

		Guaranteed Purity Level	
	Unpurified	>80%	>95%
Quantity	50-100 mg	30-50 mg	20-30 mg
10 mer	$400	$700	$1000
15 mer	$550	$850	$1150
20 mer	$800	$1200	$1600

CAN YOU SYNTHESIZE & PURIFY PEPTIDES FOR LESS?

Before you buy an automated peptide synthesizer, you should consider the actual cost for in-house synthesis which includes the cost of reagents, personnel, service contracts, analysis, purification, waste disposal, laboratory space, downtime and, of course, the initial cost of the synthesizer.

Multiple Peptide Systems

10955 John Jay Hopkins Drive, San Diego, CA 92121 USA

Telephone (619) 455-3710
FAX (619) 455-3713
Outside California (800) 338-4965

MPS also provides a unique HF Cleavage Apparatus and a complete HF Cleavage Service.

Reader Service No.595

Hi purity
ambda DNA

QIAGEN *Hi purity* >lambda< kits will dramatically change the way you isolate lambda DNA. The QIAGEN >lambda< kit series represents a complete purification system. Lambda kits are available for either Mini, Midi, or Maxi preps of lambda DNA, containing all buffers, reagents, protocols and the QIAGEN mini columns.

QIAGEN means:

High Purity DNA
Speed and Convenience
No Phenol
No CsCl or Ultracentrifugation

With QIAGEN
CsCl purity is equalled:

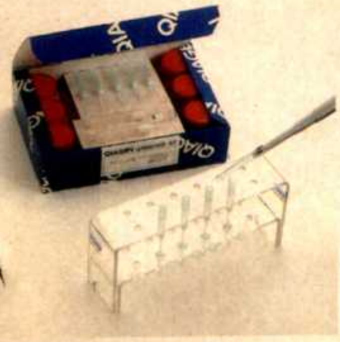
Pure lambda DNA can be isolated rapidly and economically using QIAGEN kits and easy-to-follow protocols. It is ideally suited for:

Cloning
Enzymatic processing
Sequencing

QIAGEN mini columns

contain our unique-anion-exchange resin QIAGEN that guarantees the selective isolation of different classes of nucleic acids, and the complete removal of proteins, polysaccharides and metabolites.

QIAGEN kits are now available for plasmid DNA and lambda DNA



Reader Service No.282

QIAGEN

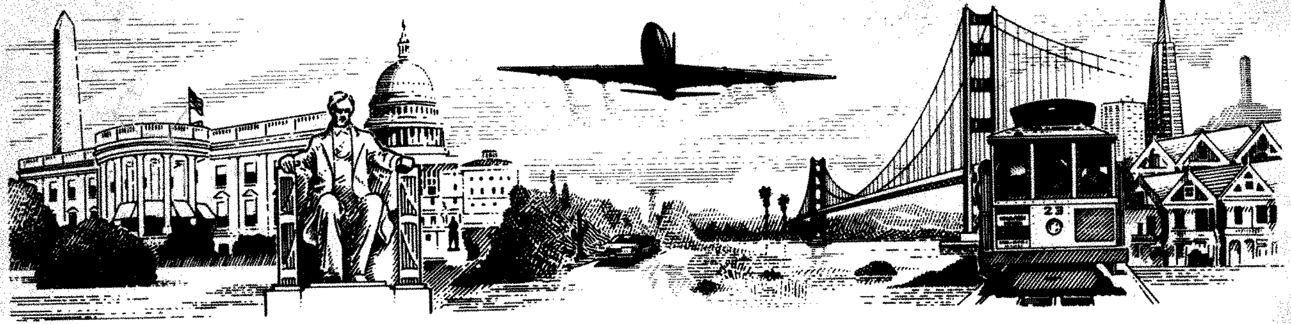
The Daily Telegraph

BRITISH ASSOCIATION

Promoting Science and Technology

Young Science Writer Awards 1990

WIN A WEEK IN THE USA



Are you aged between 16 and 28? Does the world of scientific discovery fascinate you?

Yes? Then how would you like to spend a week in the USA – at the 1991 American Association for the Advancement of Science Annual Meeting, in Washington D.C.

YOUR WRITING TALENT CAN GET YOU THERE.

We are looking for articles of about 700 words on a scientific discovery or research topic of your choice. It could be anything from astrophysics to animal behaviour or AI to HIV.

You select the field – and then write an article that both informs and entertains specialist and general newspaper readers alike.

THE PRIZES

The competition is divided into two age groups: 16-21 and 22-28, with a total of 12 prizes in each age group:

- The best article will earn its author a trip to the USA in 1991, as well as the satisfaction of seeing the winning piece published in The Daily Telegraph's Monday Science and Technology page. They will also receive an invitation to attend Science 90, the British Association's Annual Meeting, in Swansea.
- Second prize is a year's donated subscription to Nature, and a year's subscription to New Scientist, plus an invitation to Science 90. All runners-up have a chance of seeing their entries published in The Daily Telegraph.
- There are 9 runner-up prizes of a year's donated subscription to Nature, and a year's subscription to New Scientist.
- A further 25 entrants whose articles are of particular note, will be awarded The Daily Telegraph-British Association Certificate of Merit.
- In addition – for every school pupil reaching the final round of judging, a prize will be awarded to their school.

DR. ROGER HIGHFIELD'S COMPETITION GUIDE

General points:

1. Your article should be about 700 words in length, and not more than 800 words.
2. Your article should be clear and informative and understood by the non-specialist newspaper reader. Scientific jargon should either be explained or avoided.
3. If you feel diagrams or illustrations would be helpful, include them in your entry. It doesn't matter how sketchy they are.
4. 16-21 age group entrants and 22-28 age group entrants not engaged in original research: Write about any scientific discovery, for example, a project being pursued locally or perhaps topics discussed recently in scientific publications. Whatever you choose, you must identify your sources.
5. 22-28 age group entrants engaged in original research: It doesn't matter whether your research is complete or not; citing other work is perfectly acceptable if your own has not yet borne fruit.

For a more detailed guide and copies of last year's winning entries, please write to the competition address.

THE JUDGES

Professor Lewis Wolpert: President, British Association for the Advancement of Science. **Sir Walter Bodmer:** Director of Research, Imperial Cancer Research. **Mr. Richard Fifield:** Executive Editor, New Scientist Magazine. **Dr. Peter Newmark:** Nature Magazine. **Professor Sir David Phillips:** Laboratory of Molecular Biophysics, Oxford University. **Professor Heinz Wolff:** Institute of Bio Engineering, Brunel University. **Dr. Roger Highfield:** Science Editor, The Daily Telegraph. **Dr. Mary Archer:** Scientist and Company Director. The judges will assess your articles on content, quality of writing, your age, and any graphic illustrations you may propose.

Send your entry to: Ms. Julie Dallison, British Association, Fortress House, 23 Savile Row, London W1X 1AB, to arrive not later than 24 February 1990. Make sure that your entry clearly shows the category you are entering, your full name, date of birth, school/university/place of work, contact address and telephone number.

COMPETITION RULES

1. Entrants must be aged between 16 and 28 (inclusive) at 24.2.90. 2. Entries must be typed or legibly written in ink or ballpoint. 3. Entries over 800 words in length (not including description of any graphic illustration) will be disqualified. 4. The judges decision is final and no correspondence on the nature of assessment or the results will be entered into. 5. Competition is open to UK residents only. Employees (and their families) of The Daily Telegraph plc, subsidiary or associated companies, advertising and promotion agencies are not eligible. 6. The Daily Telegraph Standard Competition Rules apply. They can be obtained by sending a stamped addressed envelope to Ms. Julie Dallison at the address shown above.

nature

23 November 1989
Vol. 342 Issue no. 6248

◀ 'Science in Brazil', a 20-page feature, begins on page 355. Cover artwork: Andrew Birch. The Amazon region is also the subject of a Letter and News and Views (see panel below) and Scientific Correspondence, page 350.

THIS WEEK

No, definitely not

Exhaustive attempts by workers at the UK Atomic Energy Authority's Harwell Laboratory to reproduce the much-publicized results of Fleischmann *et al.* and Jones *et al.* have failed to support a 'cold fusion' explanation for the phenomena. Spurious effects that might contribute to apparent positive results include noise from neutron counters, cosmic rays, miscalibration of calorimeters and variable electrolytic enrichment of tritium. Page 375.

Breaking-down barriers

Mutations affecting the mismatch DNA repair system are found to increase the frequency of genetic recombination between two bacterial species — *E. coli* and *S. typhimurium* — by up to 1,000-fold, showing that this system is one of the barriers preventing genetic exchange between species. Page 396.

Vital factor

The cloning of human hepatocyte growth factor is reported on page 440. The availability of functionally active recombinant human HGF will be of value in research into liver function, and in the long-term HGF may be useful clinically for enhancing liver regeneration after surgery, and in the diagnosis and treatment of hepatitis.

More making less

Although the link between polar ozone depletion and halocarbon chemistry has been clearly established, attempts to account for the rate of ozone loss in Antarctica in terms of known photochemical processes have had limited success. Additional ozone-depleting mechanisms may therefore be involved, and photolysis of OClO is suggested as a candidate, page 405.

RNzyme specificity

The definition of the precise nature of the interactions between the guanine base of guanosine and the *Tetrahymena* self-splicing intron demonstrates the mechanism by which an RNA enzyme binds specifically to its substrate, page 391.

Ribosome switch

In the malaria parasite *Plasmodium falciparum,* two different ribosomal RNAs predominate at different stages of the life cycle. How the transition is made is investigated on page 438.

Amazonian portents

The Amazon basin contains roughly half the Earth's tropical forest. What would happen to the climate of the region if relentless deforestation were to lead to the replacement of trees with savannah and pasture? A three-year computer simulation provides some of the answers. Pages 411 and 343.

Making of a pathogen

The transfer of a cutinase gene from one fungal species to another confers the ability to infect intact fruit, providing additional evidence that this enzyme is important in enabling plant pathogens to overcome the physical barrier of the plant cuticle. Page 446.

Ear to the ground

The evolution of the middle ear is central to the discussion of how the first tetrapods adapted to life on land, and it seems that the earliest tetrapods may have retained a fish-like breathing mechanism. The morphology of the stapes bone of *Acanthostega*, a primitive tetrapod from the Upper Devonian of Greenland, suggests that it was involved in breathing movements rather than in the functioning of an impedance-matching ear. Pages 425 and 342.

Nature® (ISSN 0028-0836) is published weekly on Thursday, except the last week in December, by Macmillan Magazines Ltd (4 Little Essex Street, London WC2R 3LF). Annual subscription for USA and Canada US$295 (institutional/corporate), US$125 (individual making personal payment). USA and Canadian orders to: *Nature*, Subscription Dept, PO Box 1733, Riverton, NJ 08077-7333, USA. Other orders to *Nature*, Brunel Road, Basingstoke, Hants RG21 2XS, UK.
